Chemical (& Metallurgical) Engineering

A Technical Newspaper,
Being the Incorporation of
Electrochemical and Metallurgical Industry
and Iron and Steel Magazine

Volume XXI

From July 1 to December 31, 1919

This volume of Chemical & Metallurgical Engineering is complete in fifteen numbers owing to the fact that certain numbers so designated on their individual contents pages have been combined.

436846
3. 7. 45

NEW YORK:
McGRAW-HILL COMPANY, Inc.

INDEX TO VOLUME XXI

GENERAL ALPHABETICAL INDEX

PAGES.		AMERICAN CERAMIC SOCIETY:		B	
July 1	57 to 56	Chicago meeting. Program.	299	"Ball and ring" method for m. p. of as-	82
Aug. 1	112 to 112	Report.	462	phalt.	
Aug. 15	113 to 218	Past, present and future of. Binns.	464	Barcelona, Plans for 1920 sample fair.	440
Sept. 1	219 to 268	N.		Barrett, W., Portland cement in London	493
Sept. 15	269 to 412	American Chamber of Commerce in London		Bates College Jordan Scientific Society.	194
Oct. 1	413 to 444	to send commission to Germany.	170	BATTERIES:	
Oct. 8	445 to 476	AMERICAN CHEMICAL SOCIETY:		Primary:	
Oct. 15	477 to 554	Philadelphia meeting. Announcement	61	Dry cells. Depreciation of. Hel-	520
Oct. 22	555 to 640	Program.	226	trecht, N.	
Oct. 29-Nov. 5	641 to 694	Report.	278	Manganese dioxide in dry cells.	196
Nov. 13-Nov. 19	695 to 652	Industrial excursions.	488	Manufacture of dry cells.	196
Nov. 26-Dec. 3	653 to 700	AMERICAN ELECTROCHEMICAL SOCIETY:		Secondary:	
Dec. 10-Dec. 17	701 to 738	Chicago meeting. Program.	65	Mfr. at Electric Storage Battery Co.	490
Dec. 24-Dec. 31	739 to 796	Program. Complete.	295	Beckman & Linden Eng. Corp., Silicon-	
		Report.	520	ganese furnace.	*752
		Boston meeting (1920) Announcement	686	Belgian wage scale.	724
		AMERICAN INSTITUTE OF CHEMICAL		Belgian commercial museum wants sam-	
		ENGINEERS:		ples.	623
		Boston meeting. Report.	*5	Belgian steel trust proposed.	741
		Savannah meeting. Program.	547	Belgium, Metallurgical situation in.	154
		Report.	*600	Production statistics: (see Production	
		Photograph of members.	711	statistics).	
		AMERICAN INSTITUTE OF METALS:		Zinc industry. Chase.	571
		Philadelphia meeting. Report.	*550	Benzene. Continuous rectification of. Baril.	*693
		AMERICAN INSTITUTE OF MINING AND		(S.)	
		METALLURGICAL ENGINEERS:		Benzene stills. Barrett Co.	*494
		Chicago meeting. Announcements	170	Beryllium: (see Glucium.)	
		Program.	24, 128, 167, 296	Bessemer process (see Iron and Steel,	
		Report.	458	Processes).	
		Dinner to Herbert C. Hoover. Report.	410	Beverage Exposition.	*706
		AMERICAN IRON AND STEEL INSTITUTE:		Biometal, New Cu-Zn alloy.	632
		New York meeting. Report.	545	BIBLIOGRAPHIES:	
		Americanization work in Newark, N. J.	375	Casein and casein glues.	138
		American Petroleum Institute.	486	Caseins-kerosene mixtures. flax,	
		AMERICAN SOCIETY FOR TESTING		padding, etc.	252
		MATERIALS:		Glue, Animal and casein.	138
		New headquarters.	498	Shellac.	721
		Standards adopted in 1919.	527	Black liquor ash. Sodium hydroxide from.	
		AMERICAN STEEL TREATERS' SOCIETY:		McAfee, (P.)	*256
		Chicago convention. Announcement.	61	Blast furnace: (see also Iron and Steel,	
		Program.	299	Furnaces).	
		Report.	530	Blast-furnace gases. Recovery of potash	
		American Zinc Institute meeting.	29	from. In England. Hibbert.	723
		America's case in chemistry. Hendrick.	684	Blood-roasting: (see Roasting)	
		Aminocycene. Production and use. An-	743	Blood albumin. Jervan and van Hooen-	
		drews. (P.)		huzze. (B.P.)	404

The Dawn of Peace

WITH whatever feelings we may have contemplated the procedure of the Peace Conference at Paris, there could be but one universal sentiment at the announcement of the Germans that they were ready to sign the treaty unconditionally. Men everywhere experienced a sense of relief, a feeling that the world had at last finished a nasty job and could go about its business, could afford to take at least one eye off the enemy and apply it to works of construction. True, events immediately subsequent to the declaration showed that not more than one eye could be detached for the present, and that watchfulness would be in order for some time to come. It is true also that the world still awaits retributive justice in the trial of those responsible for the war and the payment of indemnities to ravished Belgium and France. But on the whole there is a feeling that the pursuits of peace can occupy our attention. There will still be much political debate and argument, despite Lincoln's historic and classic recognition of the fact that "the world will little care or long remember what we say here," but that need not deter industry from putting its hand to the throttle and forging ahead. The future will be determined more by work than talk.

Co-operation Between Industry and University

WE PUBLISH in another column a letter from a student of chemical engineering in which the prospectus of an intercollegiate chemical society is outlined. It has for its purpose the establishment of a course of lectures on the technology of various industries and the details of large-scale chemical apparatus. The idea seems to us worth while. There is a considerable hazard of loss in breaking in nearly every student to factory practice, and this should be decreased by the course proposed. A trouble that has not been provided for in these lectures by manufacturers, works chemists and sales engineers of apparatus is that men who are not accustomed to lecturing are fully likely not to consider their time and get to the point without needless preambles and peroration. Usually it is like pulling teeth to draw information out of an unregenerate manufacturer—and by unregenerate we mean one that fears his neighbor as the devil, and who holds that all information relating to his industry should be privy to his establishment.

What we would like to see in chemical engineering courses is better training in industrial physics. After all it is more important to know why things are done and why results ensue than to learn how to do them. It takes very little explaining to teach a man how, who knows why.

Is Molybdenum a Metallurgical Mystery?

ONE of the minor metals which has witnessed some puzzling vicissitudes in fortune during war-time is molybdenum. Ten-fold increase in price caused quadrupling of output, whereupon the market became more or less nominal, and has remained stagnant for several months. Under these circumstances, miners of this material are naturally much concerned about the chances of future business, especially since molybdenum minerals are much more widespread and accessible than others, tungsten or vanadium as instances, and any probable demand could be readily satisfied.

Contradictory statements as to its uses have been so current as to dub molybdenum "the metallurgical mystery." KRUPP did absorb a great proportion of the available supplies, and captured German gun tubes have been variously reported as containing from zero to 6 per cent. No information as to similar use by an Allied government has come to notice. While the metal has a high melting point, it is said to change very readily into a volatile oxide, so that silver plating is necessary to get the alloy into the metal rather than the slag. Some gun tubes may have been de-molybdenized by heat, other analyses may have unfortunately confounded this element with carbon, while again, still others may have always been innocent of its presence, possibly due to the high price of silver!

Seriously, though, molybdenum steel is a demonstrated success. Quantities of it have been used in aeroplane engines, while many liberty motor crank shafts were made of a manganese-chromium-molybdenum alloy. Following extensive experimentation, one prominent automobile maker in the Detroit region ordered 10,000 tons of a special alloy containing a fractional per cent molybdenum, which is being used in forged or case-hardened parts demanding high strength and low weight. As such it should replace the vanadium steels already well established, owing to the comparative rarity of vanadium and to the fact that the new alloy does not require such close control in heat treatment; perhaps molybdenum acts as a brake in spreading transformations over a wider temperature range. The addition of molybdenum to nickel steels in small quantities increases the ductility remarkably.

Such are the uses of the future. At present considerable quantities of molybdenum are absorbed by tool-steel makers—the element is almost always present in modern metal-cutting tools.

Even granting the fact that molybdenum steel is a demonstrated high-strength material, it certainly will not be a panacea for all heat-treating troubles, and it is difficult to see any great boom in molybdenite in the

near future. Mines and mills are already developed to such an extent that should their present excess capacity be put into molybdenum steel (averaging perhaps 1 per cent), 250,000 tons of this material would be produced per year. Picture the metallurgical knowledge which must be accumulated before iron-masters will be able to deliver uniform steel of this comparatively new analysis, the many obscure troubles which arise in the manufacture of the completed parts—some wholly new and baffling defect may vie with the notorious “flakes” of nickel steel in keeping metallurgists awake nights—picture the campaign of education necessary to make the purchasing agent recognize its value and the purchasing public demand minimum weight with maximum strength, and the conclusion is inevitable that widespread demand for molybdenum as a constituent for steel will not be a matter of months.

A Rose By Any Other Name—

ELSEWHERE in this issue the reader will find a communication from the house of Kuhlmann, Paris, protesting against the assumption of the German origin of its founder. Exception is taken primarily to a statement of Landis in his article on the oxidation of ammonia, to the effect that “eighty years ago Kuhlmann, a German technical chemist, etc.,” and proof is now offered that Kuhlmann was “a savant doubly French.” We are glad to give space to the correction as further evidence of the myth of German preëminence in chemistry, which is growing less persistent as the facts in the history of chemistry come to light.

If we may boldly claim in this instance to represent average American intelligence among chemists, we can readily understand how Mr. Landis and probably the great majority of our readers, would accept innocently enough and quite as a matter of fact, a statement that Kuhlmann was a German chemist. For have we not been nurtured in the belief that chemistry and Germany were synonymous, and that the abode of chemical knowledge was beyond the Rhine? Couple this with the typical spelling of Kuhlmann, and we have all the elements necessary to an erroneous conclusion. But it appears that Kuhlmann was born in Colmar, Alsace, in 1803; was subsequently professor of chemistry in the University of Lille, and later founder of the 40,000,000-franc Etablissements Kuhlmann in Paris and elsewhere in France. He was a Frenchman by birth, education and all that characterizes one's nationality and mentality.

The last five years have developed awkward situations regarding the merits of the scientific and technical contributions of the several nations. It has been easy to foster extreme views and share partisan feelings. A large number of American technical men were of foreign birth or education. German literature had been widely read in this country, and it was perhaps logical that we should have assumed that Germany had led the way in all chemical progress. We have learned, however, that names are not safe tags of identification as to the nationality and mentality of the world's scientists; and in the present instance we are delighted to know that it was a French savant who early recorded the importance of the oxidation of ammonia to nitric acid. We render unto Caesar the things that are Caesar's and acclaim a French scientist even though he bears a German name.

Need of a Firm Policy in Mexico

WITH European affairs less engrossing than they have been for several years the United States has an opportunity to turn much needed attention to its Mexican relations. They need attention! For almost 10 years the interests in American mining and metallurgical companies operating in Mexico have suffered from the lack of protection of life and property. Murder, robbery, pillage and banditry have been committed and practised without effective interference or suppression and almost without protest. If the Government has had reasons for pursuing a weak policy with our Southern neighbor those reasons have not been disclosed to the country's satisfaction, and the people are beginning to feel that it is about time to abandon patience and yield to the impulses of righteous wrath. The policy of watchful waiting finds us still watching and waiting after nearly a decade, but almost hopeless of a firm governmental policy that will insure protection to Americans and their property. Conditions have been unsettled for so long that we have almost come to regard them as inevitable and something to be endured without remedy.

But there are hopeful signs. Congress has recently pressed the Administration for a statement of its policy, and Under-Secretary of State Polk is reported to have spoken “with complete frankness” to the House Committee on Foreign Affairs, laying the Administration's cards on the table. Firing across the border into El Paso has been stopped by an excursion of American soldiers into Mexican territory, apparently with Mexico's acquiescence. Of more than ordinary importance is the action of the Mining and Metallurgical Society of America in proposing resolutions of protest

“against further disregard by the American Government of conditions in Mexico that make it unsafe for American engineers to go there in the practice of their profession and for the care of business interests intrusted to them”;

and further urging

“the American Government to take prompt and effective steps toward the establishment of such law and order in Mexico as will safeguard the persons and property of our citizens and extend its protection to all Americans in any part of the world to which they may be called in the pursuit of their legitimate affairs.”

The Society is to be commended for this evidence of interest in Mexican affairs, and we see no reason why the American Institute of Mining and Metallurgical Engineers should not go on record with similar resolutions reflecting the attitude of the great mining industry. The Institute has recently amended its charter to permit participation in public affairs and expression of opinion on public questions affecting its members. At the moment we can think of no more opportune theme for the exercise of the Institute's newly acquired powers than advocacy of a firm governmental policy in Mexico. Dignified representation to the Government by influential bodies of citizens will hasten the dawn of a new era in Mexican relations that will be mutually beneficial. The people of the United States have been more than long-suffering in this matter, not only in toleration of Mexican lapses, but in refraining from unkind criticism of the Government's policy, whatever it may be. The elements of the situation seem to be comparatively simple and the remedy effective. It is futile to talk of Mexico's national honor when our own country is humiliated and insulted.

Automatic Control Devices In the Chemical Industries

TRUE to American traditions begun by substituting the harvester for the scythe, our inventors have not failed to design automatic mechanism endowed with about as much cerebellum matter as is required in ordinary routine work. The cobbler had his destiny foretold by the experiences of the nailsmith and the weaver. Is it only a matter of time before the chemical control operator will follow suit and pass his skill to the tools of which he will be merely a tender?

Tank gaging is far better done by the hydrostatic pressure recorders now coming into vogue than was ever accomplished by the most exact calculations obtained from volume and temperature measurements. Temperature control is almost an undisputed job for the thermostat. Solution gravities, concentrations, viscosities—all are coming within the scope of the automatic control devices operated by buoyancy floats, electrolytic conductivity or resistance balances, propelling resistance recorders, and similar apparatus.

The fairest solution of the question appears to be found upon examining the experience of the artist since the era of the camera. In the early days when sensitive plates were made with asphalt-lard coatings, and turpentine was the solvent used to dissolve the parts not polymerized by light, photography appeared unlikely ever to become a member of the fine arts. However, developments came about which demonstrated that the camera shutter was not to be a portal for the exit of the artist but an arch of triumph for conquests in science as well as art. The same must be true of such devices in the hands of the engineer. He must not be satisfied with rough initial developments and, above all, must not have the feeling that he will work himself out of a job by doing what he can toward developing automatic control devices. Relief from routine work will give the chemist opportunity for larger development.

Stability of

Prices and Employment

IN time of prosperity one should prepare for adversity and *vice versa*. Business is prosperous, and is certain to be more so, for a period of years. Panics and industrial depressions can, perhaps, be prevented but the method has not yet been invented, much less put into execution. To err is human, and these occurrences result from the errors of men.

There are important new conditions, and if panics and depressions occur they will exhibit different phenomena than formerly. The Federal Reserve system, according to the judgment of experts, removes the possibility of a "money panic." The organization of labor, and the new ideals of labor, make it improbable that men will compete for work to the extent they have done in past industrial depressions. The depression of 1873-8 saw "dollar-a-day" labor, and in the depression of 20 years later there was the same development. Men are almost certain to insist, when there is not enough work for full employment, that the work be divided and hourly rates be maintained.

This change, by itself, would make an industrial depression more severe. When commodities are sold, or service rendered, whether the furnishing of electric current or the removal of dirt from one's clothes, part of the payment goes to the workmen involved and part to

the capitalist who furnishes the facilities. If the volume of business decreases and the one party stands none of the loss the other party must stand a correspondingly greater loss. When capital does not secure a return there is no creation of fresh capital such as in times of prosperity would be reinvested and make more work for the people. Moreover, if the cost of labor does not decline the inducement of cheapness to the making of investments is removed. A census of the skyscraper office buildings in the country would probably show that the majority of them were placed under contract in times of relative depression.

Recurring to the Federal Reserve system, it provides means whereby funds can be secured by those who have credit. In the past such facilities have been largely lacking. To provide absolutely necessary funds capitalists have had to operate plants at a loss, not getting a new dollar for an old one. Such performances probably will be unnecessary.

Thus in the new order of things it seems probable that when there is a tendency to industrial depression both labor and capital will refuse to work for less money reward than formerly and thus the traditional readjustment will not be encouraged. It is not intended to deny that the probable occurrence of panics, other than money panics, and of industrial depression has been reduced. It certainly has not been shown, however, that the reduction is to zero, and it does seem clear that if such things do occur the means for recovery are reduced. It is like reducing the likelihood of the human system to yield to disease but at the same time reducing its power to throw off the disease, once the infection has occurred.

Every year brings its own joys and sorrows and so do changing conditions. The outlook for the investor is not gloomy, but bright, for there is another new condition that makes capital more valuable than ever. Common labor in the United States, over periods of years, will never be as plentiful as it has been. That comes from sociological and racial conditions, not from business or financial conditions, and represents a permanent change. As less work is to be done by common labor more work must be done by capital, by the creation of plant facilities pursued to the *n*th refinement of labor-saving efficiency. Instead of there being no room for new investments there is vastly more room than ever before, since the new labor conditions make the existing facilities much less efficient, relative to the supply of labor, than formerly.

What is necessary is that the investor be able to earn enough in the first few years of operation to safeguard him in case industrial depression comes. The investor must look upon this matter from a new viewpoint. In the past his philosophy has been that he must amass sufficient extra profit to enable him to write off a large sum from the investment to cover reduction in cost of duplication. In the new order of things such declines in the cost of duplication are likely to be much less severe than formerly but on the other hand the chances of unemployment may be greater. The investor should save, therefore, against the temporary period when his investment may yield no profit. It is clear, also, that the sooner one makes his investment and begins securing returns upon it the safer he will be for the future. Delay undoubtedly means loss. The world is going to move, and move rapidly, and one should move with it.

Readers' Views and Comments

Oxidation of Ammonia

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your issue for May 1, 1919, we note an article by W. S. Landis on the Oxidation of Ammonia, in the first paragraph of which occurs the following statement:

"Eighty years ago Kuhlmann, a German technical chemist, after describing at length some very interesting experiments of his own, concluded with the significant remark, etc. . . ."

For reasons which are readily understood it is impossible for us to overlook the error in this statement regarding the nationality of Kuhlmann, who was a savant doubly French, because he was born in Colmar (Alsace) in 1803. Frederick Kuhlmann was professor of chemistry at the University of Lille, the great industrial city of Northern France, and it was there that he made a great number of researches in the domain of pure and applied chemistry.

Most of his works were first published in the Bulletin de la Société des Sciences de Lille; others in the Annales de Physique et de Chimie (de Paris).

His discovery of the oxidation of ammonia by catalysis with spongy platinum was described for the first time in a memoir entitled "Mémoire sur la Nitrification" published in Vol. 15 of the Bull. de la Soc. des Sc. de Lille which contains the reference cited by Mr. Landis.

Ingenious manufacturer as well as a great savant, Kuhlmann installed in 1825 in Lille a sulphuric acid plant, which was the cradle of the Kuhlmann plants now numbering 15 scattered all over France.

He died in 1881, correspondent member of the Académie des Sciences de Paris and Commander of the Legion of Honor.

At a time when the masterful discovery of Kuhlmann, exploited by a German, Ostwald, is justifying the prophecy of the French savant, we consider it our duty to attract the attention of our American friends to the evident involuntary error made by Mr. Landis, and we would be greatly obliged if you would make due correction in an early issue of CHEMICAL and METALLURGICAL ENGINEERING, for which we present you our thanks in anticipation.

ADMINISTRATEUR DELEGUE
ETABLISSEMENTS KUHLMANN

Paris, France.

Chemical Technology for College Students

To the Editor of Chemical & Metallurgical Engineering

SIR:—An authority on education once said that a fault of modern technical institutes was the failure of the instructors to establish proper relationship between book knowledge and practical, everyday technology. This is also true of chemistry, which brings me to the purpose of this letter.

There is in process of formation an organization called the Intercollegiate Chemical Society, the main purpose of which is to correct this condition. The following is an excerpt from the preamble to its constitution:

"It is highly desirable, especially in the undergraduate courses, to connect chemistry with the world of commerce as it has not been connected. This can easily be

done by the co-operation of students and manufacturers. Many potential chemists have been lost because the applications of science have not been made apparent in lectures or laboratory work."

The Intercollegiate Chemical Society proposes to accomplish its purpose by inducing prominent manufacturers or members of their technical staffs to lecture to its members, if possible every fortnight, showing the technology of various processes and apparatus, and indicating the applications of laboratory practice to factory control. These would be supplemented by demonstrations on trips with the students through plants, whenever practicable.

The officers of the society are prepared to send to any manufacturer who is willing to contribute aid in this connection, a calendar of subjects studied, so that demonstrations of apparatus and lectures in industry may be co-ordinated with the course. The academic calendar includes thirty weeks of actual work. This provides for fifteen such discussions or demonstrations during the year. If we can secure the co-operation of that number of manufacturers, each will be asked for but one discussion or demonstration per year.

We are organizing branches of the society in a number of universities throughout the States and the purpose of this is to ask manufacturers in the chemical and allied industries to co-operate. I have spoken to a number of men well known in industrial circles and they believe the advantage that can be derived from such a plan will prove profitable to both students and manufacturers. With such training a student will be made more efficient and can take up his duties when entering an industrial plant with less likelihood of loss and delay by the exigencies of "breaking him in."

Students should have a more thorough understanding of the needs of chemical industries. This knowledge, combined with the fundamentals gained at the university, will help them recognize and eliminate wastes and increase yields as they advance in technical development. It will be an efficient way to connect theoretical chemistry with actual industrial conditions. It will also develop a tendency for young chemists to seek methods in which the achievements of pure science may be brought ever closer to industrial practice.

If manufacturers who are interested in providing for such demonstrations of industrial practice, or of apparatus which they make, will communicate with me I shall be glad to respond with whatever additional information they may desire.

Intercollegiate Chemical Society,
Columbia University, N. Y.

H. GROSSMAN,
Acting Chairman.

Surplus Government Lead

By arrangement with the Lead Producers' Committee of the War Industries Board, sufficient orders will be allocated to the War Department to take up the surplus stock of pig lead, which does not exceed 5000 tons. In addition, about 10,000 tons of heavy sheet lead, 25 tons of lead pipe and 6 tons of lead slabs will be disposed of without the assistance of the industry. The Director of Sales is also seeking a market for 1180 tons of antimonial lead and approximately 930 tons of antimonial lead scrap.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

Meeting of American Institute of Chemical Engineers

Large Gathering at Boston and Cambridge—Interesting Visits to Places of Historical and Industrial Interest—Massachusetts Institute of Technology, A. D. Little, Inc., Harvard University—Symposium of Electric Furnaces

THE eleventh semi-annual meeting of the American Institute of Chemical Engineers at Boston and Cambridge, June 18-21, does not lend itself readily to a brief description. The excursion on the steamer "Gurnet" was the unique feature. Mr. Henry Howard, Director of the Emergency Fleet Recruiting Service and sometime of the Merrimac Chemical Co. endeavored to demonstrate by the trip to sea in the "Gurnet" just why he had such great interest in maritime pursuits. The Boston Fish Piers were visited first in order to furnish fresh material for future fish stories as well as to entrance all angling desires. About a million pounds per day of cod, haddock, mackerel, etc., were said to be the average of the season. Inspection of the cold storage department demonstrated that ample provisions have been made for many Fridays to come.

The second stop was made at the plant of the Revere Sugar Refinery. Thousands of tons of crude sugar, the Cuban in 200-lb. burlap bags and the Philippine in 50-lb. palm platted sacks, were stacked in the pier warehouses. In refining, the sugar is dissolved, limed and filtered in Sweetland presses. The syrup is then clarified by percolating it through animal charcoal and is then ready for crystallization in vacuum pans. After the grains have grown to the desired size, the sugar is discharged into open bins from which it passes into centrifugals, is freed from molasses and flushed with water sprays to remove both the finer crystals and syrup. Two or three percent of moisture remains in the centrifuged product and is removed in forty foot drum driers. The engineering involved in such a works is a model for the crystal type of chemical process. Every task is performed with a minimum expenditure of energy and labor. After the initial elevating of the crude syrup to the top floors, gravity does the rest. The packaging machinery was exceptionally good and since space does not permit more description, only the names will be given. Bag Machine: Richardson Scale Co., Passaic, N. J. Bag Sewing Mach.: Union Special Machine Co. Chicago.

Package Filler and Sealer: Pneumatic Scale Co. Norfolk Downs, Mass. Box Nailer: Morgan Machine Co. Rochester, N. Y.

While enroute to the Victory Shipbuilding plant at Squantum, the Edison Power Plant was passed. Also a brief inspection was made at the seamen training school. The visit to the Victory yard gave an excellent opportunity for a study of modern steel fabrication. Hundreds of riveting gangs put added vigor to their tasks and the red hot battered rivet heads in cooling drew the steel plates tightly together. In order that there should be no seams for water leaks at the joints, the calkers rammed the edges of the plates so that they were sprung flush. From the storage yard to the fitting out basin in a quarter of an hour was too brief a time to observe details. It is enough to say that torpedo boat destroyers will never be out of sight on our coast after a few years more of standardized fabrication.

Enthused after so many excellent plant visits along Boston harbor, the voyaging members did not seek to break away before the final event of the day—the trip out in the open water of Massachusetts Bay to Marblehead. The Gurnet being a small steamer of fifty odd feet length was soon effectively rocking and much to the satisfaction of the fishes. Of the one hundred and twenty six passengers, only half were found by the photographer the next day in happy enough condition to have their appearance registered in the annual June meeting panorama.

LABORATORIES IN CAMBRIDGE VISITED

On Wednesday night, a smoker was held in the assembly room of the A. D. Little, Inc. building. Every one was delighted with the arrangement of the laboratories and offices. The paper mill was in operation and demonstrated the facilities with which Dr. Little's staff is equipped to carry on research in most of the large industrial chemical enterprises. The museum gave

¹For description see Chem. & Met. Eng., Vol. XIX, P. 100.

additional evidence of the great scope of their work and contains specimens of the greatest value. Mr. Ellwood Hendrick gave a humorous exhibit on electron furnaces in which he transformed a mixture of saw dust and like miscellaneous materials into fresh hot roasted peanuts. The remainder of the evening was devoted to fun, refreshments and song.

The new buildings of the Massachusetts Institute of Technology are marvelously compact. The right wing of the inner court, over which the illustrious names of Pasteur and Lavoisier are carved, is devoted to the chemical departments. The laboratories are, it is needless to say, the best that could be built. It comparing the chemical engineering equipment with that of some of the other engineering laboratories, the casual visitor might think that there was room for considerable improvement. The commercial size hydraulic, steam and electric power plants make the small Swenson evaporators look small indeed and they are the giants of the industrial chemical laboratory. However, Prof. Walker has overcome these difficulties and set all the

President A. D. Little introduced an amendment to the method of selecting candidates for membership whereby the admission committee could place those candidates up for election who do not quite meet all the specifications but have real meritorious qualifications. It is hoped to make the Institute the real representative body of the American chemical technologists and engineers.

Dr. David Wesson invited the society to be his guest at Savannah, Ga., at its winter meeting. Great cotton oil and naval store plants are located there, and not least of all, Savannah is the most typical of all southern towns.

PAPERS PRESENTED

The major part of the program was assigned to the symposium on electric furnaces. Extracts from three of these papers are included below and selections from the others will be given in a future issue. The Institute semi-annual report will be published shortly giving the texts in full. The Growth and Development of the Manufacturing Plant of the Providence Gas Company

by Mr. W. H. Russell will be given in three parts. Dr. Chas. L. Palmer gave a splendid review of the gaps left in the chemical study of the wool grease. The most amusing debate was precipitated by Dr. Edward Gudeman's argument that chemists should be licensed. Dr. James R. Withrow, who was scheduled to support the issue, sidestepped the matter and Drs. A. W. Smith and David Wesson went at the argument so vehemently that the old western proverb which said, "Never stop to argue with a Smith & Wesson" certainly proved to be as wise a maxim for oratorical combats as those fought with lead.

DIVISION OF CHEMISTRY, HARVARD UNIVERSITY

other engineering divisions a new example. Technology instructors are now placed in several of the chemical plants around Boston and the students are given more than the birdseye view of the manufacturing business.

The Wolcott Gibbs Memorial Laboratory¹ is the forerunner of what might be called the Harvard College of Chemistry. A view of the group of buildings as now planned by the architect, Mr. A. W. Longfellow, is given. Dr. Morris Loeb, Mr. James Loeb, T. Jefferson Coolidge and several members of the alumni are the donors of the first two buildings. These buildings will be instrumental in the development of pure and applied chemistry for generations to come and it is certainly a rare privilege that wealth has bestowed upon the founders which will enable them to contribute so much to the future welfare of humanity. Professor T. W. Richards personally welcomed the Institute. Though he was able to show the prize points of the laboratory such as 6-ft. drawers and other extraordinary facilities for research, the guests knew that their real opportunity was in visiting America's greatest chemist in the building entirely devoted to research under his guidance.

Symposium on Electric Furnaces

The program for the symposium was arranged by Mr. C. T. Bragg of the Michigan Smelting & Refining Co. The first paper was read by H. W. Gillett, of which the following are extracts:

UTILIZATION OF ELECTRIC BRASS FURNACES

Four years ago there was no electric brass furnace in commercial operation. Today some forty firms are using or now installing approximately 100 electric brass furnaces. One rolling mill has about 30, though most of these are small 300-lb. furnaces. One smelting and refining company is using four one-ton and four three-quarter-ton furnaces. Another firm has four one-ton furnaces and the various offices of the U. S. Mint will soon have five furnaces. Batteries of two or three furnaces are quite common.

Five types of furnaces have advanced far enough so that the makers can cite truly commercial performances. Various other types are in the experimental or semi-commercial stage but are not yet on the market, and a few are on the market with some at least of the experimental troubles left for the purchaser. While recogniz-

¹For full description see Harvard Alumni Bulletin, Vol. XV, No. 26, P. 424-429.

ing that there is yet no perfect electric brass furnace, and that future development may produce a type superior to those now in commercial use, prospective users may properly pay first attention only to the types which have been commercially proven in users' hands.

These types are (1) Direct arc type, with the Snyder as the only make as yet really used on copper alloys out of the dozen of that type that are used for steel, (2) the vertical ring induction furnace type (Ajax Wyatt), (3) the granular resistor, reflected heat type (Baily), (4) the stationary indirect arc type (Rennerfelt), and (5) the indirect ore type with stirring of the melt (rocking furnace). Clamer,¹ Baily,² vom Baur,³ Miller,⁴ the writer,⁵ and especially St. John⁶ have previously discussed the possibilities and limitations of these various types and a mere summary is sufficient here.

The Ajax-Wyatt is the most efficient in use of power, uses up no electrodes, gives thorough mixing of the charge, perfect temperature control, and has the steadiest electrical load. It must be "primed" with previously melted metal after a shut-down and hence is not well fitted for 10-hour operation, though it can be used on 10-hour operation by keeping some current on and holding some metal molten overnight. The need for "priming" makes it difficult to change from one alloy to another. It has been mainly used on yellow brass, though it is applicable to red. Its greatest drawback is that so far no refractory lining has been found that will satisfactorily withstand the action of alloys containing over 3 per cent lead. It is best fitted for 24-hour operation on the same alloy. It could be mechanically charged.

The Baily is the least efficient in use of power, does not mix the charge, but has a steady electrical load

and uses up no electrodes. This type cannot be powered as high as others without grave danger to the resistor troughs, and is hence at a disadvantage as to efficient use of power, especially on alloys of high melting point. It is best fitted for 24-hour operation. When used for 10-hour operation it is usually necessary to put power on part of the night to keep the empty furnace hot. It is not readily charged mechanically. It has poor temperature control, due to its heat storage and consequent sluggishness. It can be used on any alloy but is better fitted for yellow brass than for the higher melting alloys. Its greatest advantage is its simplicity of operation.

The Snyder or any other direct arc furnace is applicable only to true bronzes or other alloys low in zinc, 5 per cent zinc being the probable limit. It is entirely impractical for use on alloys high in zinc. The only installation used for copper alloys is used on leaded bearing bronze, the new lead being added in the ladle. Much lead is volatilized from the scrap in the charge, and much fume results, giving bad working conditions. The installation of Snyder furnaces has a very poor power factor, though this is not necessary in a direct arc furnace.

The greatest advantage of the Snyder furnace in its limited field is its adaptability to mechanical charging, which aids in securing large output and hence in reasonable power consumption. One drawback is the single-phase arc load.

The Rennerfelt or any other stationary indirect arc furnace is most applicable to alloys low in zinc. It has been used on alloys up to 22 per cent zinc with fair results, but as the zinc increases above 10 per cent the metal losses increase, and 10 per cent zinc is probably the economical limit of its application. It has met with decided success in melting cupro-nickel, bronze and silver at the Mint. It is not readily charged by mechanical means. The power consumption is fairly low.

The rocking type of indirect arc furnace is applicable to alloys of any zinc content, gives a low power consumption, is apparently efficient in small as well as large sizes, can readily be mechanically charged, has good temperature control and mixes the charge thor-

TABLE I. PERFORMANCE OF ELECTRIC BRASS FURNACES

Name	Type	Power Supply Kw.	Charge Lb.	Power Factor	Material	Output-Tons per Day on Material Given		Power Consumption Kw.-Hr. per Ton on Material and Time of Operation	Consumption of Graphite Electrodes Lb. per Ton
						10-hr. Operation	24-hr. Operation		
Ajax-Wyatt	Vertical ring induction	30	300	85	Yellow brass	1 to 1½		300-350*	None
		30	300	85	Yellow brass		3 to 3½	225-310	None
		60	600	72	Yellow brass	2½ to 3		250-300*	None
		60	600	72	Yellow brass		6 to 7	185-250	None
Baily	Granular resistor	105	800-1500	98-100	Yellow brass	2½ to 3½		400-500*	None
		105	800-1500	98-100	Yellow brass	2½ to 3		450-550*	None
		105	800-1500	98-100	Red brass		6-10	275-350	None
Snyder	Direct arc	100	600	35-70	Leaded bearing bronze	1½		380	—(Experimental)
		300	2000	30-60	Leaded bearing bronze		12-18	260-320	3-5
Rennerfelt	Indirect arc	100	500	75-90	Red brass	1½		450-500	3-6
		125	1000	75-90	Bronze	2 to 2½		375-425	3-5
		125	1000	75-90	Bronze		7-10	325-375	3-5
Rocking	Indirect arc	300	2000	75-90	Leaded bearing bronze		10-16	300-350	3-5
		40	125	80-90	Red brass	1		400	—(Experimental)
		225	1300	80-90	Red brass	3½		325-340	2½ to 4
		225	1300	80-90	Red brass		8½	250-275	2½ to 4
		300	2000	80-90	Red brass	6 to 7		275-325	2½ to 4
		300	2000	80-90	Red brass		16-20	225-275	2½ to 4
		300	2000	80-90	Yellow brass		6 to 7	250-300	2½ to 4
		300	2000	80-90	Yellow brass		16-20	200-250	2½ to 4

oughly. Its drawbacks are the single-phase arc load and the possibility of electrode breakage in rocking too early if unskillfully operated.

The performance of the various furnaces properly operated may be expected to lie in the ranges set forth in Table I.

The figures in Table I do not in all cases agree with the catalog claims of the makers of the furnaces, as they are based on data obtained both from makers and users. The output and power consumption depend not only on the analysis of the charge, but also on the condition of it, i.e., whether all ingot, heavy scrap, light scrap, borings, or mixtures, as well as on the way the furnace is operated, just as gasoline consumption varies with the roads and the way the car is run. It will be noted that there is a wide variation in power consumption among the various types of furnaces, and that for the same type, the efficiency increases with the size.

If the types of furnaces unfit for use on alloys high in volatile metals are confined to use on alloys free from or sufficiently low in such metals, and if the furnaces are kept tightly closed after the charge is melted, all types of electric furnaces will give very low metal losses indeed. No fuel-fired furnaces can compete with properly chosen electric furnaces on this score. Of course, the lost metal is mainly zinc and lead, so that the value of the loss in fuel-fired furnaces is not as great as it would at first sight appear to be when the percentage loss is considered. This loss, however, usually amounts to about as much as the fuel or labor cost, and, even with cheap zinc and lead, is worth eliminating.

In making a choice of furnaces the user must first

eliminate those types which will not operate satisfactorily on alloys he must melt in them, for example, the rolling mills making yellow brass would thus eliminate the direct arc and un-rocked indirect arc furnaces, and the makers of alloys high in lead and the people who must change from one alloy to another often would eliminate the Ajax-Wyatt. The user should then select from the remainder the type and size of furnace which will best fit his particular work. If he has very cheap power available, the granular resistor type may be chosen over a more efficient arc furnace because of the avoidance of electrode consumption. Where power is high, the balance would be against the granular resistor type. One rolling mill may prefer to continue to pour very small billets and may find the Ajax-Wyatt exactly suited to its needs. Another may wish to operate on a larger scale and may find a one-ton rocking furnace more suitable. A maker of bronze who must take his power from a very small power plant may find that a single-phase arc load would be unacceptable to the central station and hence might choose the two-phase Rennerfelt instead of the single-phase rocking furnace.

The size of furnace chosen will depend on the output desired and on whether 10- or 24-hour operation is called for. While the largest size furnace that can be kept busy should be used, it is poor economy to purchase a large furnace and then operate it with charges much under its capacity or to allow it to lie idle a good share of the time.

An electric furnace is expensive in first cost. The one or two furnaces required to melt 5 tons per day on ten-hour operation will cost from \$10,000 to \$20,000

completely installed. For purposes of calculation assume the cost to be \$15,000. At 300 days per year the output is 1500 tons. Taking interest at 6 per cent, the interest is \$900 per year or \$3.00 per working day, this amount being lost every day the furnace is idle. At full output the interest charge is 60c. per ton.

On the other hand, if one furnace costing \$10,000 is operated for 300 days per year 24 hours a day with an output of 16 tons, the total output is 4800 tons, and daily interest charge \$2.00 per day, or 12½c. per ton.

On account of the initial cost and the interest charge, one should in general not have electric furnaces standing idle to handle small peaks of production in excess of the normal, but should utilize for this fuel-fired furnaces of lower initial cost.

On the other hand, the greater the number of electric furnaces which can be kept busy the lower the cost of power per ton.

BASIS OF POWER RATES

Industrial power contracts usually have two factors, the demand charge and the energy charge. The first pays the power company for the equipment it must maintain to supply the maximum power needed, while the second depends on the total amount of power used.

Suppose we have a maximum demand of 300 kw. and that the average power consumption per ton of metal is 335 kw.-hr. per ton on 9-hour operation, 275 on 18-hour, and 250 on 24-hour. The total power used per day is then about 2000, 3565, or 5250 for the three cases. In a 25-day month this makes 50,000, 91,000 and 130,000 kw.-hr. per month.

Assume that the plant, before it installed its electric

furnace equipment, had a maximum demand in lights and motors, of 200 kw., and used 20,000 kw.-hr. per month for those purposes. Taking a concrete case where the power contract calls for a demand charge of \$1.80 per kw. per month for the first 50 kw. and \$1.00 per kw. per month for all over 50 kw., and the energy charge schedule is

2500 kw.-hr. per month at 2.0c. per kw.-hr.	
for the next 35,000 kw.-hr. per month at 0.8c. per kw.-hr.	
for the next 310,000 kw.-hr. per month at 0.5c. per kw.-hr.	
all over 347,500 kw.-hr. per month at 0.4c. per kw.-hr.	
The 200 kw.-20,000 kw.-hr. lighting and motor power cost	
50 × \$1.50 = \$75.00	2,500 × 2 0c. = \$50 00
150 × 1 00 = 150.00	17,500 × 0 8c. = 140 00
\$225 00 demand	\$190 00 energy charge

Total \$415.00 or 2 07½c. per kw.-hr. used.
The plant now has 500 kw.-hr. maximum demand, and 70,000, 111,000, 150,000 kw.-hr. used per month on the three assumptions.

50 × \$1.50 = \$75.00	
450 × 1 00 = 450.00	
\$525 00 demand	
Energy—case 1—2,500 × 2 0 = \$50 00	
35,000 × 0 8 = 280 00	
32,500 × 0 5 = 162.50	
70,000	\$492 50 energy
	525 00 demand
	\$1017 50 total charge
less	415 00 previous charge for lights and motors
	\$602 50 total charge for electric furnace power

$$\frac{602.50}{70,000} = 0.861\text{c.}$$

The electric furnace costs 0.860 c. per kw.-hr.

In case 2 we have the same demand charge, but the energy charge is

2,500 × 2.0 =	\$50.00
35,000 × 0.8 =	280.00
73,500 × 0.5 =	367.50

111,000	\$697.50 energy
	525.00 demand

	\$1222.50 total
less	415.00 lights and motors

\$807.50 total charge for furnace power

807.50

— = 0.89

91,000

The furnace power costs 0.89c. per kw.-hr.

In case 3 we have

2,500 × 2.0 =	\$50.00
35,000 × 0.8 =	280.00
112,500 × 0.5 =	562.50

	\$892.50 energy
	525.00 demand

	\$1417.50 total
less	415.00 lights and motors

\$1002.50 total charge for furnace power

1,002.50

— = 0.79c

130,000

The furnace power costs 0.79c. per kw.-hr.

And, if in case 4 the plant had three times the furnace installation figured above and used it 24 hours a day, or 900 kw. furnace demand 1100 kw. total, 450,000 kw.-hr. per month furnace energy, 470,000 total, the charge would figure

50 × 1.50	75.00	\$2370.00 energy
1050 × 1.00	1050.00	1125.00

	\$1125.00 demand	\$3495.00 total
--	------------------	-----------------

25.00 × 2.0 =	\$50.00	less 415.00 lights, motors
		\$3080.00 total for furnace power

35,000 × 0.8 =	280.00	3,080.00
310,000 × 0.5 =	1550.00	= 0.685c.
122,500 × 0.4 =	490.00	450,000

\$2370.00 energy	The electric furnace
power costs 0.685c. per kw.-hr.	

Tabulating these we get Table II.

TABLE II.

Case.....	1	2	3	4
Hours.....	9	18	24	24
No. furnaces.....	1	1	1	3
Kw.-hr. per ton.....	335	275	250	250
Power price per kw.-hr.....	.860	0.89c.	0.79c.	0.685c.
Cost per ton for power.....	\$3.92	\$2.45	\$1.98	\$1.71

This table shows the advantage of continuous operation of electric furnaces, as well as that of large installations. The exact figures will vary in each particular case, but the ratios will remain approximately the same.

The elimination of delays will give a 25 per cent increase in output in an hour's less time, and decreases the cost of power per ton by about 40c.

The cost of power is in most cases the largest single item in melting costs in electric-furnace practice. Every effort must then be put forth to keep this cost down. The way to do this is to keep the furnace at work at its job, which is melting metal. This is important on 24-hour operation, but even more so on 8- to 10-hour operation, for an extra heat per day on single-shift operation means that it is obtained at the end of the day when the furnace has recovered from cooling off through the night. Any furnace will illustrate this fact. Take an actual day's run of a small Rennerfelt on red brass for example.

Heat	Charge Lb.	Total Time	Arc On	Idle Time	Kw.- Hr. Used	Kw.-Hr. per 100 Lb.	Notes
1	497	2:45	2:05	40	211	42	Furnace at red heat from previous day's run.
2	522	1:45	1:25	20	130	25	Delay waiting for molds.
3	527	2:55	1:10	1:45	105	20	
4	525	1:25	1:05	20	106	20	
5	394	1:25	1:10	15	94	25	Waiting for molds, so held power input low.
2,463		10:15	6:55	3:20	646	26	Av. or 520 kw.-hr. per ton

This could have been run as follows, by eliminating all delays:

Heat	Charge, Lb.	Total Time	Arc On	Idle Time Charging and Pouring	Kw.- Hr.	Kw.-Hr. per 100 Lb.
1	525	2:10	1:55	10	215	41
2	525	1:40	1:25	15	150	25
3	525	1:25	1:10	15	105	20
4	525	1:20	1:05	15	100	19
5	525	1:20	1:05	15	100	19
6	525	1:20	1:05	15	100	19
3,150		9:15	7:45	1:30	750	24 av. or 480 per ton

With the exception of the granular resistor type in which it is difficult to hold metal after it is once ready to pour because the response to changes in power input is so slow, it is possible to hold metal ready to pour as long as one likes in any of the electric furnaces. This is a convenience in an emergency, but it is very poor practice from the point of view of furnace efficiency.

In addition to using efficient discharging and charging devices, another way that power can be saved in electric melting is to operate on a definite schedule of power used. The Ajax-Wyatt takes power at so steady a rate that a time schedule works just as well on that type, but the granular resistor furnace and the arc furnaces may vary considerably in rate of power input. After a few test runs, one can, for any particular alloy, particular proportion of ingot, scrap and borings, and for any particular weight of charge, make out a perfectly definite schedule of kw.-hr. needed on each heat. In 10-hour operation the kw.-hr. per heat will be higher in the morning and approach or reach a lower constant figure at the end of the day.

By adhering to such a schedule and running on kw.-hr. input instead of on a time schedule at a supposedly constant but actually variable kw. input, the heat can be brought out with astonishing regularity as to temperature. Each furnace should have its individual kw.-hr. meter, and one readable to certainly not less than 5 kw.-hr., and better 1 kw.-hr. With individual kw.-hr. meters the performance of each furnace in a battery, and of each furnace tender can be watched.

Inasmuch as the heat losses through the walls and the electrodes are approximately constant even though the rate of power input may change, it is obvious that the higher the rate of power input, the more of it is usefully employed in melting. Suppose a furnace takes 100 kw. and loses 35 kw. through shell radiation and electrode losses, 65 kw.-hr. then do useful work. If the same furnace is given 125 kw. it may lose 37½ kw. in shell and electrode losses, but 87½ kw. do useful work. The furnace will do one-third more work in a given time at the higher rate. The upper limit of rate of input is that at which the local temperature is so high that refractories fail or that local overheating of the metal and consequent loss of volatile metals occur. It is quite probable that on the larger furnaces automatic control of power input would be desirable.

ELECTRIC FURNACES OF THE RESISTANCE TYPE

Mr. T. E. Bailey illustrated his paper with moving pictures. The following are selections from his paper:

The principal factors taken into consideration as necessary to the development of a successful brass melting furnace were (1) the metallurgical requirements (2) the mechanical features (3) the electrical characteristics (4) the thermal efficiency (5) the commercial economy as compared with other types of melting equipment.

The obvious advantages to be found in an ideal electric furnace over fuel fired types for melting were (1) the elimination of crucibles, which are one of the principal costs in the melting of brass in pit type furnaces (2) the reduction in metal loss when handling zinc mixtures, on account of the slight vacuum under which all pit type furnaces are required to operate (3) the inability to maintain a reducing atmosphere in the furnace when operating with any degree of fuel efficiency, and (4) the fact that copper alloys, as well as copper, have a high affinity for the absorption of undesirable gases when in their molten condition, this being equally true of other alloys and non ferrous metals, such as aluminum.

Before the development of these furnaces for brass melting, a careful survey was made as to the adaptability of the more common types of furnaces then widely in use in the melting of steel, to determine whether such furnaces could be readily and successfully adapted for brass and other non ferrous melting operations; and if they could be, with what degree of commercial efficiency, as compared with the resistance type of furnace we then had under consideration.

When considering the use of the true resistance type furnace as it might be applied to the melting of non ferrous metals, the following points were given consideration

(1) That the metal should be contained on a true open hearth, and that the heating element should be entirely independent of the metal.

(2) That the heating element should be such that there would be a comparatively slight difference in temperature between this heating element and the bath, so as to overcome the objectionable features offered by the arc type furnace.

(3) That it should be feasible to tightly close the furnace in order to keep the molten metal under a pressure, however slight, and to prevent, as well, any draft of air through the furnace chamber.

(4) That the electrical characteristics of the furnace as applied to power factor should be such as to overcome the objections present in the induction furnace, and that the wide power variation present in the arc furnace should be, if possible, eliminated.

(5) That the furnace should not be subject to rapid changes in temperature from the most desirable ruling temperature for any particular melting operation.

(6) That the furnace should be as compact as possible, in order to reduce radiation losses to a minimum.

In this latter case, while the resistance type furnaces about to be described require a somewhat larger shell for a given melting capacity than either the arc or induction furnace, the absence of the highly localized temperature does not produce such a serious condition with regard to refractories; and the lower temperature with which the resistance element in a resistance type furnace operates, enables a higher degree of heat insulation to be used, so that the thermal efficiency of resistance type furnaces compares favorably with other types—with the exception, perhaps, of the induction

furnace, whose higher thermal efficiency is seriously offset by its higher renewal and repair cost.

One of the mechanical features taken into consideration before determining on the type of furnace to be used was whether it was necessary, in order to obtain perfect alloying, to provide some oscillating motion, such as was originally used on the Stassano stool furnace; but when considering that substantially all copper alloys, with the exception perhaps of lead, diffuse completely when the proper temperature and melting conditions are reached, this additional complication was dispensed with, the only agitation required being the stirring in of the spelter previous to pouring, and this stirring is only required in order to facilitate the more rapid diffusion of the alloy.

The only materials in the furnace described in this paper that need regular renewal are

(1) the resistor troughs themselves, which are made of carborundum, fire sand and water glass, and were formerly tamped into place in the furnace with the aid of wooden forms, but are now made in sections at our works and baked ready for placing into the furnaces;

(2) the electrodes for leading the current from the cable terminals through the furnace walls and into the resistor material;

(3) the resistor material itself, which consists of broken carbon crushed to about $\frac{1}{4}$ " mesh.

Under average working conditions, the fire sand troughs, and a pair of electrodes will last from three to four months, while the resistor material requires additions to it of fresh material every two weeks. This latter is accomplished in the small tilting furnace by raising the roof through the medium of three screws which are operated simultaneously by a hand wheel on the back of the furnace operated through sprockets and mitre gearing.

Some months ago for a period of time, some difficulty was experienced with resistor troughs, but a careful and exhaustive investigation brought to light that this trouble was experienced only when the analysis of the fire sand indicated an imperfect mix; and since all this material must now pass laboratory inspection, no difficulty is experienced from this source.

The furnaces now to be described are built in two regular types, the first, which has found wide applications in foundries, is of the round tilting type; while the other, of rectangular shape, is the type used for melting large tonnages and for smelting operations.

The round type is provided with a circular resistor trough with the electrodes coming into the trough diametrically opposite each other, the resistor material being renewed by lifting the roof, as previously stated; while in the rectangular type, the resistor troughs are two in number and placed longitudinally along each side of the hearth, and are, therefore, straight. The resistor material, in this case, is charged by means of long shovels through a door at each end of the furnace and directly above the trough. This furnace is a standard 105 K.W. trunion type with a rated hearth capacity of 1500 pounds and a melting rate of 600 pounds per hour. These capacities, however, have been in numerous cases materially exceeded, as much as 2 tons having been placed in a furnace at a time, and the melting rate increased to more than 1000 pounds per hour, when operating under exceptionally favorable conditions.

This furnace consists of a steel shell made of $\frac{1}{4}$ " plate seven feet in diameter and approximately 6' high, mounted on the usual cast iron trunions and brackets, and having the usual hand wheel tilting mechanism.

The interior wall of the furnace is substantially $5\frac{1}{2}$ " in diameter, with a wall of circular brick about $4\frac{1}{2}$ " thick. The space between the brick wall and the steel shell is filled with kieselguhr insulation. The steel roofing is adopted to hold securely the skew backs of the domed arch, and is provided with a lower fin for dipping into the sand seal. The space above the trough dome and below the steel top is also filled with kieselguhr in the same manner as between the fire brick walls and the steel shell of the furnace proper.

The hearth is located in the bottom of the furnace and is composed of a mixture of carborundum fire sand and plastic clay material bonded with silicate of soda. The resistor trough is located above the bath and completely encircles the rim of the hearth line, although located a considerable distance above it, and is set on fire brick piers, so that the heat from the lower part of the fire sand trough is readily dissipated from this part of the trough within the furnace chamber.

This feature is of vital importance in the successful design and operation of resistance type furnaces, as all early experiments with furnaces of this type without this feature resulted in failure.

The resistor material contained in this trough, and into which the electricity is introduced by means of the two carbon electrodes, as previously mentioned, radiates the heat generated in it to the roof of the furnace and thence down onto the hearth; while the heat coming from the lower part of the trough between the supporting pillars, is also radiated directly to the bath. That this resistor ring has a radiating surface of over forty square feet accounts for the fact that there is no highly localized temperature in this furnace.

The control of the furnace is obtained by means of impressing the various voltages on the low tension side of a special transformer across the furnace terminals by means of a special selective oil break switch. The special transformer supplied with each furnace is wound for any convenient line voltage, while the secondary of the transformer is provided with various voltage taps, usually giving a voltage ratio of two to one on the low tension side. By means of this arrangement, the electrical losses are reduced to a minimum, and an accuracy of control obtained that is not possible by other types of equipment, and it is readily possible to operate over long periods of time without a greater variation in electrical input than a few per cent.

The only opening to the furnace, which is used for charging the material is provided with a swing type plug door, the hinges being made of cast steel and attached to the furnace shell in a rugged manner. The pouring spout is a groove underneath the door, which enables the molten material to be poured without opening the door, the door itself being opened only during the charging or rabbling time. A false door, consisting of a ribbed cast iron plate, is also provided, so that when the main plug type door is open during the charging or rabbling operations, this false door can be dropped down, shielding the operator from the direct heat of the furnace interior.

This 7" diameter furnace is also built in a nose tilting type, and is operated by means of a motor driven screw mechanism at the rear of the furnace. In this type of equipment the charging door is placed at the rear and a small opening arranged at the front for pouring the molten metal. This is a type of equipment that is particularly well adapted for pouring directly into molds,

and is especially well adapted to casting rolling mill slabs, when used in connection with a rotary casting table.

The casting table is adapted for a vertical adjustment of 40" for taking care of molds of different heights, and its turning motion is imparted by means of a motor driven vertical pinion engaging a circular rack attached to the movable table, the molds being attached to the top of the table in the usual manner.

The furnace is provided with a single resistor trough located directly above the bath, with the electrodes entering at the side. This type furnace is particularly well adapted to the smaller foundries or plants where a wide variety of mixtures are handled in relatively small quantities. The electrical characteristics of this furnace are similar to those of the furnaces just described.

Of the stationary non-tilting furnaces referred to in the fore part of this paper, the smaller size is of 500 K. W. capacity, and is adapted to hold 10 tons of brass or 3 tons of aluminum. This furnace has a resistor trough of the usual type located at each side of the bath, which is supported on the usual fire brick pillars. The doors in this case are located at each end of the furnace and are of the sand sealed type.

The furnaces described in this paper are the results of years of experience, first in the development and operation of furnaces for the annealing and heat treating of steel, and later a wide experience over the last several years in furnaces built especially for the melting of brass and other non-ferrous alloys, which it is believed will find a wide application throughout the non-ferrous industry, not only in brass foundries and rolling mills, but also in melting and refining in smelters. This is particularly true of the furnace described for melting cathode inc, which it is believed will find a wide application in the melting of cathode copper, which latter operation has been accomplished in furnaces of this type without the usual blowing and poling necessary in refining; and producing copper wire bar or ingot of substantially the same analysis as the copper cathode, the finished bar or billet, having only that amount of sulphur contained on the cathode as charged and coming from the electrolyte.

As an example of what may be accomplished and of the comparative amounts of sulphur contained on the edges of the cathode sheets as compared with the center, a quantity of copper cathode was obtained and the edges of the sheet to a depth of about 2 in. sheared off. This material was melted in one of our standard 105 K.W. furnaces and cast into pig. The analysis of the bars so cast is shown in Table A below, while the result from the melting of the inner part of the sheet are shown in

Table B.

TABLE A

Analysis:

99.904 Cu. .084 O. .0021 S. Conductivity 100.1

TABLE B

99.950 Cu. .036 O. .0012 S. Conductivity 100.8

In the remelting of clean scrap, wire and similar substantially pure copper materials, it is found that this clean scrap can be remelted without any deterioration in the quality whatever, and furnaces of the character described in this paper will undoubtedly shortly come into general use for not only the melting of copper cathodes, but for the remelting of rolling mill scrap as well.

In the development of these melting furnaces constant attention has been paid to such features as were

deemed necessary for the production of equipment that could operate over long periods of time without shut down, having good electrical characteristics, convenient and accurate control of both the metallurgical and thermal characteristics, and which could at all times operate under reasonably high efficiency, but no attempt has been made to sacrifice the qualities of ruggedness of design and reliability of operation to the mere consideration of current consumption under test conditions.

ROCKING ELECTRIC ARC FURNACE

Mr. H. M. St. John reviewed the factors involved and then showed how this type of furnace fitted them as follows:

The rocking electric furnace consists essentially of a cylindrical steel shell, lined with suitable refractories, and mounted on rollers and ring gears which permit it to be rocked through any desired arc of revolution up to a maximum of 200 deg. This rocking motion is actuated by a small induction motor through a reducing gear immersed in oil and enclosed in a tight gear case. The action of the motor is controlled by an automatic reversing switch which may readily be set to give the desired angle of rock. The source of heat is an electric arc between horizontal graphite electrodes axially placed in the furnace and meeting at the center of the cylindrical melting chamber. These electrodes are controlled by hand wheels which permit them to be entirely withdrawn from the furnace chamber when so desired. One of these electrodes is set in such a way as to locate the arc approximately at the center of the furnace and is thereafter allowed to remain stationary, while the operator controls the arc by adjustment of the other electrode.

During charging the electrodes are withdrawn until their tips are flush with the inner wall of the furnace in order to avoid striking them with heavy pieces of metal which might cause breakage. The furnace is then closed, the electrodes brought to the operating position, and the arc started. During the first few minutes of the melting period the furnace is not rocking, since rocking at this stage is unnecessary and might cause electrode breakage if started prematurely. As the metal becomes soft, rocking is started, through a small angle at first and reaching a maximum rock as the metal becomes completely molten and enters the superheating stage. During this complete rock the molten metal washes the inner lining of the furnace to within a few inches of the charging door at either end of the oscillation, at the rate of approximately two complete oscillations per minute.

When the charge is molten, it lies in the lower half of the furnace cylinder at a distance of from seven to ten inches from the arc. The metal is heated by conduction from the entire refractory lining as well as by direct radiation from the arc. The stirring action due to the constant rocking motion of the furnace is sufficiently effective to maintain a constant temperature throughout the melt and thus prevent the surface overheating which would result if the furnace were stationary.

When the melt has reached the desired pouring temperature, the arc is broken and the metal is poured through the spout beneath the charging door. The door itself is not opened until the furnace is ready to charge. If, for any reason, it is impossible to pour the metal immediately, the charge may be held in the furnace with-

out danger of overheating, since no part of the furnace structure is appreciably hotter than the metal. If desired, rocking may be continued during this period, in order to insure a perfectly uniform temperature and a thorough mixture of the alloying metals.

The indirect arc lends itself excellently to the maintenance of a uniform power input and a steady electrical load. After a little experience the operator learns to judge from the kilowatt-hour input, how to adjust the rocking of the furnace and when the metal is hot enough to pour. In other words, he knows what condition the metal is in by observing from his meter how many kilowatt-hours of heat he has put into the furnace. This is the most convenient and satisfactory method of controlling the temperature, as well as the heat input, and works extremely well, even with an operator of very mediocre intelligence.

The reliability of the furnace is high, since its construction is both simple and rugged. Its cylindrical form permits the strongest possible refractory structure; the method of heat generation is simple and involves no complicated parts, electrical or otherwise; the gears and other parts of the rocking mechanism are sturdy and not exposed to high temperatures, while the electrical control mechanism is as simple as it can be made and very seldom a source of trouble. There is nothing complicated about the controls and even the greenest of operators rapidly becomes proficient in their use.

The power input of the furnace is relatively large and its thermal efficiency high, this desirable combination resulting in a high productive capacity. The arc is not more than ten inches from the metal on a full charge, while it is approximately eighteen inches distant from the nearest refractories—the vertical and walls—and 20 inches from the cylindrical walls. This makes possible a rapid rate of heating without injury to the refractories, while overheating of the surface layer of the metal nearest to the arc is prevented by the constant mixing which it undergoes. Using 2000 lb. charges, the rocking furnace will produce approximately 2000 lb. of molten brass per hour, melting time, or about 1500 lb. per hour, elapsed time, the latter including time consumed in charging, pouring, and incidental delays. This is a higher productive capacity than can be obtained with any other electrical brass-melting furnace of similar size.

The quality of the metal produced is a function of temperature control, thorough mixing, and the absence of impurities. Any electric furnace which does not burn the metal makes possible the avoidance of impurities and thus compare favorably with fuel-fired furnaces, which expose the metal to a rapidly moving oxidizing atmosphere which also contains sulphur and other undesirable products of combustion.

Accurate temperature control is difficult in those types of electric furnaces which heat their refractory walls and roofs far above the metal temperatures, thus causing the metal to absorb heat even after the electric current has been turned off. In an arc furnace the heat input stops immediately when the switch is opened and metal can be held in the furnace indefinitely without danger of overheating.

In the rocking furnace a perfect mixture of the metals which go to make up the alloy can readily be attained, by virtue of the brisk agitation which the molten metal receives. Even high-lead alloys can be poured

from the furnace in perfectly homogeneous mixtures. The table below shows the results obtained with a series of heats, from which samples were taken of the first ingot from the first ladle and the last ingot from the last ladle in each case. The variation in composition from heat to heat was due to the selective absorption of lead by a green furnace lining. While the variation in lead content between the first and last ingots of any heat is very small it will be noted that, in three cases out of four, the percentage of lead in the first ingot is higher than that in the last.

TABLE I.

Heat No.	Ladle No.	Per Cent Cu	Per Cent Sn	Per Cent Sb	Per Cent Pb	Per Cent Zn Plus Impurities

	Last	66.01	4.47	0.61	25.67	3.04

It is, of course, frequently very important to duplicate a complex alloy, for heat after heat, with a minimum deviation from the specified composition. Table II shows how exactly this can be done with the rocking furnace. The figures given in the table are taken, not from a special test, but from the routine analysis for thirteen consecutive heats from a rocking furnace melting phosphor bronze.

The thermal efficiency of the rocking furnace is high, and the energy consumption per ton of metal melted is correspondingly low. The thermal efficiency of the furnace is considerably higher than that of any stationary type of indirect-arc furnace, even higher than that of the direct-arc furnace. It is more nearly comparable to the efficiency of the induction furnace which, since the source of its heat is in the resistance of the metal itself, does not heat its refractories to a temperature higher than that of the metal and consequently enjoys the advantage of minimum radiation losses, as well as an utter absence of electrode heat losses. The high efficiency of the rocking furnace is primarily due to the fact that approximately four-fifths of the inner refractory lining is washed by molten metal, due to the rocking action of the furnace. Most of that part of the lining which is exposed to direct radiation of heat from the arc, and thereby becomes hotter than the metal, is intermittently brought into contact with the latter and gives up its excess heat to the metal instead of expending it uselessly through the outer walls. The furnace refractories are thus subjected to

a constant cooling action and are maintained at a relatively low temperature, with the result that radiation losses are a minimum, appreciably lower than would be the case if the furnace were operated in a stationary position.

The comparatively low refractory temperature in the rocking furnace makes it possible to obtain a high thermal efficiency without an excessive thickness of heat-insulating wall. As a result, the temperature lag of the furnace is moderate and, when operating from 8 to 10 hours per day, the furnace reaches its maximum efficiency on the third heat of the day, an important consideration in intermittent electric furnace operation.

The number of kilowatt hours required per ton of metal varies widely, depending upon operating conditions and upon the nature of the alloy melted. One large rolling mill, operating the furnace 16 hours per day of 60-40 brass, gets a minimum consumption of less than 200 kw.-hrs. per ton and has averaged 224 kw.-hrs. over a total of several hundred heats. Average 8 to 10 hour operation on clean scrap and new metal mixture shows about 250 kw.-hrs. for yellow alloys, and 275 kw.-hrs. for red alloys. If a high proportion—over 50 per cent—of very oily or wet borings and grindings are included in the charge, the energy consumption on 2000 lb. charges may run as high as 300 kw.-hrs. per ton.

The ability to handle very dirty borings and fine scrap of all kinds, whether red or yellow, is an advantage peculiar to the rocking furnace. It is possible in this furnace to melt satisfactorily a charge consisting wholly of dirty yellow borings and grindings, without opening the furnace after melting begins, something which can hardly be done in any other furnace without mechanical rabbling accompanied by high metal loss.

Although as already mentioned, the labor cost per furnace-day with furnaces of similar size does not vary greatly from one electric furnace to another, the high productive capacity of the rocking furnace makes possible a very low labor cost per ton of metal melted.

The importance of the metal saving effected by any properly designed and correctly operated electric furnace is well recognized. In the rocking furnace clean yellow brass can be melted with a net loss below one per cent. With red mixtures the net loss is, of course, less than with yellow metal, usually not above 0.5 per cent. Borings and fine dirty scrap can be melted with far less loss than is the case in any type of fuel-fired furnace, or in any type of electric furnace where mechanical rabbling is necessary, although the loss is, of course, higher than with clean scrap or new metal mixtures. Metal losses under two per cent when melting very dirty borings and cuttings are by no means unusual, this with metal which must ordinarily be melted in a reverberatory furnace, with complete loss of the volatile constituents of the alloy. Red borings, if not too dirty, can be melted with a loss practically as low as that experienced with clean red scrap or new metal.

The rocking furnace has introduced one decided innovation in brass foundry practice. With this furnace it is not only possible, but even highly desirable, to add spelter with the rest of the charge at the beginning of the heat, when melting new metal or making up a deficiency of zinc in a scrap charge. This not only saves the time ordinarily consumed by the speltering operation but also avoids the necessity of opening the

furnace for this purpose, with the attendant loss of metal and heat. Tin and lead should also be added with the rest of the charge rather than at the end of the heat.

The excellent showing made by the rocking furnace, as compared with other types of arc furnaces, with respect to metal loss, is due to the rocking motion of the furnace, with the resultant agitation of the metal which eliminates all danger of local overheating of the charge.

The rocking feature of the furnace also plays an important part in prolonging the useful life of the refractory furnace lining. The continual washing to which most of the lining is subjected cools the refractories to a temperature only slightly above that of the metal itself, well below the critical temperature of the refractory brick used. The brick selected for this service is of such a nature that erosion by the constantly moving metal is not a serious factor. A single lining of corundite brick lasts for about 350 heats in average practice, at which time it requires more or less extensive patching. Under normal conditions it is never necessary to entirely replace this inner lining, while the intermediate and outer linings ordinarily require no attention. One user of the furnace reports having obtained 600 heats from his first lining, on intermittent operation, and states that he expects to obtain from 900 to 1100 heats on continuous operation. Under average conditions the refractory cost is less than \$0.50 per ton of metal melted.

The electrode consumption is from 2 to 3 lb. per ton of metal melted, or, at present prices, from \$0.50 to \$0.75 per ton of metal. This compares very favorably with the best arc furnace practice in such installations as use the stationary type of arc furnace for melting copper alloys.

The overhead cost of melting with the rocking furnace is low, particularly in such installations as take full advantage of its inherently high productive capacity. The first cost of any electric furnace is rather high and the canny user will see to it that the furnace is busy melting metal for as many hours in each day as his manufacturing schedule will permit.

One more point which is of particular interest for the central-station company and others who supply power for electric furnace use: The electrical characteristics of the rocking furnace are such as to cause the furnace to be considered a highly desirable power load. As compared with arc furnaces in use for steel melting, its demand is exceptionally steady and free from violent fluctuations, while its average power factor is from 85 to 95 per cent. Its maximum demand is less than 300 kw. and the load which it imposes on the power line is so steady as to result in little or no inconvenience to the average central-station company or to those of its customers who may take power from the same line.

Cohune Nut Industry

In the search for materials suitable for the manufacture of gas-mask charcoal, the War Department found that the cohune (or corozo) nut, which yields a charcoal of high absorptive power, could be obtained in large quantities from Honduras. It was also discovered that the kernel of this nut contains an oil which is said to be superior to coconut oil and finds a ready sale as a high-grade cooking oil.

Attention is directed in Commerce Reports, June 6, 1919, p. 1230, to the fact that the extensive field of

these nut-bearing trees found in the Aguán River Valley in Honduras is capable of yielding 10,000 tons of nuts a month, with a working force of 500 men.

It must be remembered that, if we desire to secure a permanent market for our products in South and Central America, we must, in turn, endeavor to utilize more of the raw materials which these countries have to offer and thus aid in the development of their natural resources.

The Present Status of Labor in the English Chemical Industry

BY A. E. MARSHALL

IN PRE-WAR days in England, labor costs in the production of any of the staple chemicals were not the subject of very careful consideration by factory managers. Labor was plentiful and cheap, and as a result of the continuous excess supply, labor invariably, under the stimulus of retaining its hold on a job, was efficient.

All this has changed, and today the most important item in costs is labor. Very little attention had been paid, prior to 1914, to the use of labor-saving devices, and the plants were of such design that many of the standard forms of mechanical equipment, such as find use in the American industry, could not be utilized.

Factories erected during the war have had incorporated in their design a considerable amount of mechanical equipment, but in most cases these factories are not readily capable of change from specialized war products to staple chemicals, so that factory equipment as a whole is little in advance of pre-war conditions.

As a direct outcome of the discovery during the war of the power it possessed, labor has changed its former subservient relationship to capital, as represented by the factory owners, and at this present time it has apparent control of the industries. Hours have been shortened, rates of pay have been greatly increased, and the men no longer feel that there is any necessity of doing a real day's work. It takes more men to perform a given operation now than it did in pre-war times, and as rates are up at least 120 per cent, the resulting increase in cost of production can be imagined. One manufacturer told me that whereas his labor cost on a certain product was 11c. per 100 lb. before the war, it was now in excess of 30c., and likely to go even a shade higher.

There is a feeling of unrest in the factories which is not confined to the workmen, but extends to the salaried staffs, who have always before them the contrast of inefficient labor paid at high rates, and their own high living costs, high income tax rates, and only slightly increased salaries. As an instance of the general complaint in this direction, recent papers carried letters from a Judge and a Bishop, each presenting a budget of his expenses, and each proving rather conclusively that he could not make both ends meet without a substantial change in his pre-war salary.

Labor in the chemical industry was not organized before the war, as the only attempt to form a union (in 1895) failed through lack of support. Now there is a fairly strong union body, with about 40,000 members, affiliated with the National Federation of General Workers. A ballot is to be taken shortly by this union on the question of handing in notices to enforce 12 hours pay for 8-hour shifts with a 44-hour week, and there does not seem to be much doubt as to the result being in favor of the strike notices. So the path of the manufacturer seems to have difficulties present and ahead.

One totally unexpected feature is the disappearance of women from the industry. While the war was in progress, the English newspapers which reached America carried column after column about women who had

found a niche in industry. Every trade opened its formerly closed gates to the woman worker, and by general consent women were conceded a permanent place in the industrial world. And now, before even demobilization is complete, women's hold on the industries has slipped, and without an apparent struggle the woman worker has been dispossessed and a man has her place. There are of course minor exceptions, but in the factories which were staffed by men in the pre-war days, women have done their day and service and are already passing into a remembrance. One friend, showing me through his plant, said: "I had over 200 women in this department from late '15 to early this year—but now I haven't one." He had no explanation as to why or where his women workers had gone, and he had too many other troubles to waste time on any abstruse speculations, the simple fact being that they had gone.

Another factory I have just visited was busy during the war in the manufacture of scientific apparatus. I had heard of this factory as an example of the development of women workers to a high state of efficiency, but I found only four women left, and men, incompetent because of inexperience, turning out work that was obviously crude.

So one of the questions which agitated England during the war, "What shall be done with women in the industries?" has quietly solved itself, and it is well within the bounds of past experience for the present labor difficulties to adjust themselves and disappear. A thoughtful labor man with a wide acquaintance among the labor leaders in various industries said in the course of conversation: "The workingman has every present intention of getting more pay for less work, and this is the direct result of the extravagant expenditures of the war profiteers, but the only solution I can see to the coming industrial crisis is increased work during the shorter hours our members have already secured."

Four years of war, four years of tense production, have brought in their train an inevitable slackness among the workers due to the removal of the stimulus, and just like a case of bodily overstrain, the recovery will have to be by gradual stages. Herein lies one of the dangers to the English chemical manufacturer. The change in the relationship between capital and labor has made his position indeed unenviable, as while the present high ocean freights protect his home market they prevent him from entering his high-labor-cost products into export competition.

Chemical manufacturers generally express their present fears of American competition in the export trade, and in the domestic trade as soon as transatlantic freights drop from their present high levels. There is a definite trend observable, even in the most casual talks with manufacturers, toward protective tariffs, and it seems certain that attempts will be made to preserve the domestic trade to English chemical manufacturers by the adoption of some form of protection.

London, England.

The United States Government Chlorine-Caustic Soda Plant at Edgewood Arsenal, Edgewood, Maryland

The Largest Chlorine Plant in the World—History of the Design, Building and Operation—Brine Purification Plant—Cell Installation, Concentration and Fusion Department—Chlorine Drier and Equipment—Caustic Soda

By SAMUEL M. GREEN

SOON after the declaration of war against Germany, the War Department decided upon a very extensive poison-gas offense program. After much study of this comparatively new method of warfare, it was decided to build a Government plant for the purpose of manufacturing poison gases of all varieties and for filling the gas shells, bombs, hand grenades, etc.

Chlorine is the base from which practically every gas is made which is used in warfare. The War Department evidently expected to secure the required amount of chlorine gas from private plants, but as the gas program developed it became evident that the supply from such sources would be inadequate. The construction of the Government plant for the manufacture of poison gas, known as Edgewood Arsenal, was started in the fall of 1917. This arsenal is located about twenty miles north of Baltimore, Md., on Government property.

Manufacturers of electrolytic chlorine cells were requested late in December, 1917, to submit bids for the building of chlorine plants with capacities of from 15 to 200 tons. It was finally decided to build a plant having a capacity of 100 tons of chlorine gas per 24 hours, locating it at Edgewood Arsenal.

On March 3, 1918, the Procurement Division awarded a contract to the Warner Chemical Co. of New York, which owns the Nelson electrolytic chlorine-caustic soda patents¹, provided that it should furnish the United States Government 1776 Nelson 1000-ampere electrolytic chlorine-caustic soda cell units complete f.o.b. point of manufacture, having a guaranteed capacity of 50 tons of chlorine per 24 hours; that it furnish through the Samuel M. Green Co., engineers, of Springfield, Mass., complete plans and specifications for the buildings for the boilers, evaporators, Nelson cells, salt storage and preparation, caustic soda fusion, weak caustic storage, general stores and administration; complete specifications and plans for all auxiliary apparatus and piping, the buildings and auxiliary apparatus to be designed for a capacity of 100 tons of chlorine per day; that the company should arrange for supervision of

construction of buildings and installation of apparatus by the officials of the Samuel M. Green Co. and for the general supervision of the starting and operation of the plant by H. R. Nelson, inventor of the Nelson cell, and Samuel M. Green, president of the Samuel M. Green Co., until such time as all guarantees had been fulfilled and the plant was being successfully operated by the Government officials.

The contract required that one-quarter of the total number of cells should be shipped on June, July, August and September 7, and that shipments should be anticipated as much as possible, the Government agreeing to provide for the installation of the cells as and when received.

In order that at least a small experienced force of men should have the necessary knowledge for installing and operating the plant, the Government agreed to furnish enlisted men who were to be sent at Government expense to the plant of the Warner-Klipstein Chemical Co., located at Charleston, W. Va., operator of a large Nelson cell plant, the Warner Chemical Co. agreeing that these men should be given every facility to acquire the special knowledge required for operating such a plant.

This arrangement solved the most difficult problem facing the engineers: i.e., an experienced operating organization. Its successful solution was largely due to the enthusiasm and splendid work of the officers and men who were sent to Charleston and to their untiring work at Edgewood during the installation and starting of the plant.

No definite action was taken by the Government in regard to the second 50-ton chlorine cell plant until about April 5, when Col. William H. Walker, commanding officer of Edgewood Arsenal, informed the engineers that it had been definitely decided to proceed with its installation. The award for the additional cells was placed with the Warner Chemical Co. on June 15, and this contract called for the delivery of one-quarter of the total number of 1776 cells on Nov. 1, 1918; Dec. 1, 1918; Jan. 1, 1919, and Feb. 1, 1919.

The entire number of cells called for by the first

¹U. S. Patents 929,469; 1,149,210 and 1,149,211.

contract were delivered and erected ready for operation by Sept. 1, and the entire number of cells called for by the second contract were delivered and more than one-half of them were erected before the signing of the armistice.

Under the contract, it devolved upon H. R. Nelson and Samuel M. Green to devote practically their entire time to this project, for they were made entirely responsible for the design of the plant, supervision of its building and installation and its subsequent operation.

The Foundation Co. of New York was awarded the contract for building the chlorine plant in accordance with the plans and specifications and under the supervision of the engineers.

Lieut. Col. E. B. Ellicott, representing the Construction Division of the War Department, was placed in charge of the work, and to his great ability and untiring effort the success of the undertaking was largely due. The Construction Division in Washington drew off all quantities from the plans and purchased the materials.

Considering that it was almost impossible to secure labor in adequate quantity or quality; that it was constantly changing; the difficulties incident to divided authority between two organizations—one responsible for purchase and the other for the erection of materials; and other difficulties of those most strenuous times, the rapidity of the construction of this plant reflects great credit upon the Foundation Co.

The auxiliary apparatus for the plant was purchased under the direction of Col. Charles N. Black upon specifications furnished by the engineers. The purchase

and control of the delivery of this apparatus was finally placed under the direction of the main office of Edgewood Arsenal, located at Baltimore, Md.

During the fall and winter of 1917 and 1918, work was in progress at Edgewood Arsenal on the buildings for the chemical plant for the manufacture of toxic gases, for the filling of gas shells, and housing for officers and men. On March 5, 1918, it was decided to locate the chlorine plant near the chemical plant then in process of construction, and plans of the general arrangement of the buildings were immediately made. On March 27, however, it was decided to place the chlorine plant about 1800 ft. from the chemical plant.

ELECTRICAL INSTALLATION

Sargent & Lundy, engineers, of Chicago, Ill., designed and supervised the installation of the electrical equipment for supplying direct current to the electrolytic cells.

The Government entered into a contract with the Pennsylvania Water & Power Co. to supply 20,000 kw. at 60,000 volts over a high tension transmission line ten miles long. A 20,000-kw. steam power plant was also built on Bush River to act as a reserve, but it was not completed before the signing of the armistice. Current was supplied to the cells from a rotary converter installation located between the cell buildings.

The generating apparatus consisted of the necessary transformers, switching arrangements and twenty-four 2000-amp. and two 4000-amp., 300-volt rotary converters of the booster type. Each 2000-amp. rotary converter supplied current to two cell circuits, each circuit containing 74 cell units. The 4000-amp. rotaries were

FIG. 1. GROUND PLAN OF THE CHLORINE-CAUSTIC SODA PLANT

FIG. 2 BRINE PURIFICATION TANKS

to be used as spare units and were purchased because they could be secured before the 2000-amp. units could be obtained. The maximum direct current required to operate the 3552 cell units would have been somewhat less than 14,000 kw. when the plant was producing 100 tons of chlorine gas per 24 hours.

The electrical current for the operation of the auxiliary apparatus and for lighting the plant was supplied from a power plant located near the filling and chemical plant. This power plant supplied current at 60 cycle and it was considered advisable to use this, as the current from the Public Service system was 25 cycle and it was found impossible to secure standard motors at this frequency within a reasonable time.

GENERAL ARRANGEMENT

The chlorine plant buildings, a ground plan of which is shown in Fig. 1, consisted of a salt storage and treating building, two cell buildings, a rotary converter building, a building for machine shop and general stores, a high tension transformer yard, a boiler, power and evaporator building, weak caustic liquor storage tanks, a water pumping building and spray cooling pond, a caustic fusion building, and a drum making, caustic cooling and shipping building.

In connection with the chlorine plant, there was also constructed a liquefying plant for chlorine, a sulphur chloride making and sulphur distilling plant. This equipment was located about 1800 ft. from the chlorine plant and near the chemical plant.

SALT STORAGE AND TREATING BUILDING

The salt storage and treating building, Fig. 2, was located on ground much below the cell building's elevation and allowing the railroad to enter the building on the top of the salt storage tanks. These tanks were constructed of concrete. There were seven of these tanks, each 34 ft. long, 28 ft. wide and 20 ft. deep, having a capacity for storing 4000 tons of salt. There would have been 200 tons of salt used per day when the plant was running at full capacity. The salt was shoveled directly from the cars into these bins, an automatic grain shovel being provided for this purpose.

On the bottom of each tank distributing pipes for dissolving water supply were installed, and at the top of each, at the end next to the building, there was an overflow trough and skimmer board arranged so that the dissolving water, after flowing up through the salt, overflowed into this trough and then into a piping system and into either of two collecting tanks.

The piping system for delivering dissolving water to the storage tanks and for collecting the brine from the tanks was arranged so that dissolving water could be delivered to any tank, returned to one of the collecting tanks, and then be delivered to another storage tank and back to the second collecting tank. This arrangement was made so that all of the salt in any storage tank could be dissolved, and if the brine was not fully saturated it could be passed through another storage tank containing a deep body of salt and thereby be fully saturated. The saturated brine was pumped from the collecting tanks to any one of 24 treating tanks. Each of these tanks had a capacity of 72,000 gallons.

The eighth concrete storage bin was used for the storage of soda ash used in treating the saturated brine. Soda ash was delivered from the cars into this bin and was delivered from the bin on the floor level of the salt building to the soda ash dissolving tanks. From these tanks, the solution was pumped in desired quantity to any one of the 24 treating tanks. After the

FIG. 1 CHLORINE CELL BUILDING DRYING TOWERS AND PIPE LINE

FIG. 4. CELL ROOM, SIX BANKS OF 74 CELLS EACH

brine was treated and settled, the clear, saturated brine was drawn from the treating tanks through decanting pipes and delivered by pumps to any one of four neutralizing tanks.

These tanks were located next to a platform on the level of the car body, above the top of the salt storage bins, and hydrochloric acid was delivered directly from the cars to this platform, providing a large storage capacity for this acid. The platform level was about 30 in. below the level of the top of the neutralizing tanks and the acid was easily dumped into the tanks from the carboys. It was at first expected that the acid would be purchased, but it was finally decided to make it by the use of chlorine and hydrogen from the cells, and a plant for this purpose was designed and erected.

The neutralized brine was delivered from the tanks by a pump to a tank located at a height above the floor so that the brine would flow by gravity to the cells in the cell buildings. This tank was kept at a constant level by use of float valves and gave a constant hydraulic head to the cell feeding devices. The floor of the salt building was of concrete provided with open drains leading into a large concrete sump. Any leakage of brine was thus collected and returned to the system. The entire tank equipment was of wood and was purchased from and erected by the John Eppler Co., Baltimore, Md. The work was carried out in a most excellent manner, as is evidenced by the fact that there was practically no leakage. There was a chemical laboratory in one corner of the building for the chemical control of the brine. Two acid tanks were installed in this building, into which the weak sulphuric acid from the chlorine gas drying equipment in the cell buildings flowed by gravity. As these tanks filled, they were

emptied into tank cars on the track above the salt storage tanks, and these cars delivered the acid to an acid drying plant located near the chemical plant. The acid after being dried was returned to the cell buildings for re-use.

ELECTROLYTIC CELL BUILDINGS

There are two cell buildings, each 541 ft. long by 82 ft. wide and separated by partitions into four sections containing six cell circuits of 74 cell units. Each section is a complete unit in itself, provided with separate gas pump, drying and cooling equipment, and has a guaranteed capacity of 12.5 tons of chlorine gas per 24 hours.

The gas piping from the individual cell units to and including the drying equipment is of chemical stoneware. The piping was designed so that the gas could be drawn from the cells through the drying equipment at as near atmospheric pressure as possible in order that the gas could be kept as free of air as possible. When operating, the suction at the pump was kept at $\frac{1}{16}$ in. or less of water. The quality of the gas was guaranteed under the contract to contain at least 95 per cent Cl₂ and during the operation it was maintained at 98.5 to 99 per cent. The gas cooler design is shown in Fig. 5. These coolers were very effective, the gas being cooled to within 1 deg. of the temperature of the cooling water.

The drying apparatus consisted of a stoneware tower of special design containing a large number of plates, giving a very large acid exposure. There was practically no loss of vacuum through the drying tower and cooler. The stoneware equipment furnished by the General Ceramics Co. of New York was of the most satisfactory character. The gas pumping equipment for

each section consisted of two hydro turbine pumps using sulphuric acid as the compressing medium. They were direct connected to variable speed motors. (See Fig. 6.) The acid was cooled by circulation through a double pipe cooler similar to those used in refrigerating work. The pumps were made by the Nash Engineering Co. of South Norwalk, Conn. The gas was delivered under about 5 lb. pressure into large receiving tanks located just outside the pump rooms, and from these tanks into steel pipe mains which conducted the gas to the chemical plant, a distance of about 1800 ft. Three mains were provided and connected so that one was held in reserve to be used if repairs became necessary.

NELSON ELECTROLYTIC CELL

Each Nelson electrolytic cell* unit consists of a complete fabricated steel tank; a perforated steel diaphragm spot welded to supporting angle irons; sectionalized machined plate gas dome; fourteen pieces $2\frac{1}{2}$ in. diameter, 12 in. long, and fourteen pieces of $4 \times 4 \times 17$ in. Acheson graphite electrodes; anode supporting pins; sufficient asbestos cloth and paper for the diaphragms; copper bus bars; copper connectors from cell to cell; copper ears to connect the angle iron supports of the perforated steel diaphragm; glass insulator supports for the steel tanks; glass cells for caustic, condensation and chlorine

*A detailed description of the Nelson electrolytic chlorine cell will be published as a separate article in a subsequent issue.—EDITOR.

FIG. 5 GREEN STONEWARE CHLORINE COOLER

gas discharge; hard and soft rubber tubing and rubber stoppers, bolts, nuts and washers; and automatic feed.

Each Nelson cell unit is guaranteed to produce 60 lb. of chlorine gas and 65 lb. of caustic soda, using not in excess of 120 lb. of NaCl (salt) per 24 hr., the gas to be at least 95 per cent pure. These guarantees were largely exceeded.

The salt solution from the cell feed tank, located in the salt treating building, flows by gravity through a piping system located in a trench running the length of each cell building, and is delivered to each cell unit through an automatic feeding device which maintains a constant liquor level in the cathode compartment.

The solution percolates from the cathode compartment through the asbestos diaphragm into the anode compartment and flows from the end of the cell, con-

FIG. 6. HYDROTURBINE OPERATING AT EDGEWOOD ARSENAL (INSERT, CROSS-SECTION)

FIG. 7. EVAPORATOR BUILDING

taining from 8 per cent to 12 per cent caustic soda admixed with 16 per cent to 14 per cent salt, into an open trough and into a pipe in the trench, and through this pipe it flows by gravity to the weak caustic storage tanks located near the caustic evaporator building. These tanks were made of concrete for it was practically impossible to secure steel for tanks.

BOILER AND EVAPORATOR BUILDING

The boiler and evaporator building is on the same level as the salt treating building. Owing to natural grade of the ground, a railroad trestle was built between the salt treating building and the boiler house, and coal was dumped by gravity into this natural coal pocket.

The boiler house contained eight 500-hp. Wickes vertical water tube boilers built by the Wickes Boiler Co., Saginaw, Mich., each equipped with a mechanical stoker built by the Detroit Stoker Co. of Detroit, Mich. The boiler house was designed for a complete automatic coal and ash handling equipment, but owing to the probable temporary operation of this plant it was not considered advisable to make the investment required for this equipment. The coal was handled by a crane with a grab bucket, delivering it into a small hopper situated at such a height that coal cars operated by hand could be run under the hopper, the cars being on a level with

the top of the automatic stokers. The ash was delivered into a car and pushed to an ash pile by manual labor.

In a room next to the boiler room (see Fig. 8), there was located a feed water heater, two large horizontal air compressors for furnishing air for agitating the brine and for handling acids, etc., two refrigerating machines for producing cold water to cool the chlorine gas, and two 750-kw. alternating-current steam turbo generating units.

The chemical and filling plants required a large amount of power, and it was therefore thought advisable to install steam turbines at the chlorine plant to operate in synchronism with the turbines at the chemical plant. The turbines at the chlorine plant operated with 160 lb. steam pressure and exhausted against 20 lb. back pressure, the exhaust steam being used by the caustic evaporators.

The total steam required by the evaporators would have produced about 1500 kw. per hour, and as the turbines were operated in synchronism with the large power units located at the chemical plant, the quantity of steam delivered by the turbines could be regulated to the exact amount required by the evaporators, and the power produced was at an exceedingly small fuel cost. This arrangement would have proved of great advantage, for it was found that the power provided at the chemical plant was not sufficient for the requirements

and the power produced by the back pressure turbines was at very small expenditure.

CAUSTIC EVAPORATOR

The caustic evaporators were furnished by the Zarembo Co. of Buffalo, N. Y. The equipment consisted of six 108-in. double effect evaporators arranged on each side of the center of the building and under a traveling crane. Each set of six bodies was arranged to operate as three double effects and was connected to one large barometric condenser.

The water supplied for these condensers was from a cooling pond made by a natural depression in the ground outside of the evaporator building. The soil was of red clay, practically impervious to moisture, and therefore nothing had to be done to make a pond except clearing the ground of vegetation. The water from the condensers flowed by gravity to a centrifugal pump which delivered it to the spray heads, flowing from the pond back to another pump which delivered it back to the condenser. Caustic coolers were provided for cooling the caustic as it came from the evaporators.

Back of each line of evaporators there were four steel tanks of a capacity of 79,000 gal. each, for receiving the concentrated caustic liquor and storing it before it passed to the fusion building. The pumping equipment in the fusion building for handling weak and concentrated caustic liquor consisted of centrifugal pumps directly connected to motors. They were installed practically in duplicate so as to insure continuous operation.

CAUSTIC FUSION AND DRUM MAKING BUILDINGS

The caustic fusion building is located near the evaporator building and is arranged for 36 caustic fusion pots set in two rows. Thirty pots were installed.

The pot floor is about 7 ft. above the firing floor and on a level with the drum making building. Over each row of pots there are two cranes with a capacity of fifteen tons and one ton respectively. These cranes are on separate tracks, the small one being located below the large one. The large crane was for handling the pots, and the small one for handling the centrifugal pumps which were provided for emptying the fused caustic from the pots into the drums.

The drum-making building is located near the fusion building, and a railroad track comes to it with the ear-floor level with the building-floor. The end of this building next to the track was provided with a brick floor and used for cooling filled caustic drums. The rest of this building was used for drum making machinery, storage of steel and drum manufacture.

Motor-operated elevating trucks were provided for handling empty and filled drums. Steel skids were provided carrying six drums each. The truck picked up these skids and transported them to the caustic pots. They were filled with caustic by the pump provided for this purpose; then they were transported to the drum making building, where they were allowed to cool while still on the steel skid. When cool, they were delivered to cars and shipped.

SULPHUR CHLORIDE PLANT

A method was devised for the manufacture of mustard gas by the use of sulphur chloride. It therefore became necessary to manufacture a large amount of this chemical. The engineers were instructed to design a plant for the manufacture of sulphur chloride and the method devised by Mr. H. R. Nelson was used. The design of this plant was started about June 15 and the plant was put in successful operation September 1, 1919.

FIG. 8. PUMP HOUSE, AIR COMPRESSORS AND TURBINES

FIG. 9. CAUSTIC FUSION AND DRUM CHARGING BUILDING

LIQUID CHLORINE PLANT

It was decided that it would be best to build a plant for the liquefaction of chlorine gas to insure a pure supply of chlorine for manufacture of phosgene gas and to supply liquid chlorine for certain types of gas shell.

Owing to the fact that the Nelson cell produced such a very high quality of gas, it was found that it was not necessary to liquefy the chlorine for use in manufacture of phosgene. The liquefying plant was constructed from details furnished the Government by the Mathieson Alkali Co. of Niagara Falls, and the plant was erected under the direct supervision of Lieut. Col. Charles F. Vaughn, who came from the Mathieson Alkali Co. and was placed in charge of the chlorine gas plant. This plant was placed in operation just before the signing of the armistice.

The contract for the design of the chlorine plant was awarded on March 3, 1918. Definite location of the plant was decided March 27. The railroad track for serving the plant was completed May 8. Ground was broken for the shop building May 10. The first circuit of cells was ready to operate Aug. 1.

The first section of No. 1 cell building, having a capacity of 12.5 tons of chlorine gas per 24 hours, was started in operation Sept. 1, the circuits in this section being put in operation as rapidly as the chemical plant could absorb the gas. There were no difficulties encountered in starting, and operation was continued until the signing of the armistice. The plans furnished by the engineers were carried out without any changes during or after construction, and their estimates of cost would not have been exceeded had it not been for the extraordinary cost of labor due to high wages, much overtime and inefficiency.

The success of the entire work at Edgewood Arsenal was largely due to the great executive ability and personal force of Col. William H. Walker, upon whose shoulders rested the entire responsibility. All of his associates will remember him with admiration and respect.

Samuel M. Green Co.
Springfield, Mass.

American Institute of Mining and Metallurgical Engineers, Chicago Meeting

PLANs for the meeting of the American Institute of Mining and Metallurgical Engineers at Chicago next September are assuming definite form, and the committee in charge announces the following schedule of events:

On Monday, Sept. 22, the opening day, the morning will be devoted to registration of members and guests at the convention headquarters, the Congress Hotel. Monday afternoon the first session for presentation and discussion of technical papers will be held, and in the evening a smoker, at which the committee guarantees all traces of glaciation will be dissipated.

It is planned to make an excursion on Tuesday in a body, by a boat chartered for the occasion, across the south end of the lake to Gary, for a trip through the famous steel mills. Wednesday will be devoted to technical sessions, morning and afternoon, and in the evening the banquet will be held at the Congress Hotel, at which all members of the Institute and their wives will be the guests of Chicago.

On Thursday, a special train will convey the members and guests to La Salle and Depue, Ill., where the zinc smelters, coal mines and cement works will be visited. For those to whom these industrial operations are not of particular interest—this may include many of the ladies—there will be a trip by automobile to Starved Rock and other points of historical interest in the vicinity of La Salle.

For Friday, several optional excursions have been planned to local industrial plants. One trip will take in the lead refineries at East Chicago and the Standard Oil Refinery at Whiting. Another excursion will be to Milwaukee, to the plants of the Allis-Chalmers Co. and the Power Mining Machinery Co.; this trip will also include the metallurgical works at North Chicago of the Fansteel Products Co., where novel electrothermal processes in the production of metallic tungsten, molybdenum, cerium, and tantalum will be demonstrated.

For those interested in coal mining it is planned to have an excursion to the fields in Franklin and McCoupin Counties, leaving Chicago late Friday evening and spending Saturday at the mines.

Importation of German Scientific Books

In order to obtain a license for the importation of scientific books or journals which were printed in Germany, it will be necessary to deposit the purchase price with the American Relief Administration, so that the money may be available for the purchase of foodstuffs for Germany. The duplicate receipt issued by the American Relief Administration must be submitted to the Bureau of Imports of the War Trade Board when the application for the license is filed.

Removal of Tin Import Restrictions—Correction

The dates for shipment from point of origin and for entry have been changed by a recent War Trade Board ruling from those given in *CHEMICAL AND METALLURGICAL ENGINEERING*, June 15, 1919, p. 638, to June 30 and Aug. 1, 1919, respectively. Licenses for the purchase of tin are no longer required.

New and Rapid Apparatus for Electrochemical Analyses

By J. T. KING*

IT HAS long been recognized in electrochemical analysis that agitation of the electrolyte hastens deposition of the metals. In an effort to keep pace with the modern demand of more speed in analysis, many mechanical devices and artifices have been introduced, employing the agitation principle. The best known types of these employ rotating anode, rotating cathode, rotating paddle, solenoid, and air streams. Analyses which formerly required many hours can now be satisfactorily performed in a few minutes. This saving in time has so revolutionized the usefulness of many electrolytic methods that the old objection of the time required can no longer in fairness be held against them.

While observing some of the apparatus employing moving electrolytes in operation, it occurred to the writer that stirring an electrolyte by rotating its containing beaker would be a more suitable and efficient method of agitation than others then in use. A careful search of the literature showed that no apparatus employing this principle had been described. The only

beakers stood in a cup $\frac{1}{2}$ in. in depth. The lower part of the stands was weighted with lead, to impart stability when the upper part was in contact with the belt. Not over 60 r.p.m. could be used, as the beakers wobbled badly because of the small lateral support given by the cups. To overcome this the cups were increased in depth, when it was found that interference with the electrodes rendered difficult the operation of placing the beakers in position, also their removal. The cells were short circuited by inserting a metal plug between the electrode holders. Considerable speed and dexterity were essential in removing a cell with its stand, and introducing the plug, so that the current would not be broken while any of the cathodes with their plating were in contact with the acid solutions. Without rotation it required 10 hours to plate 1 g. of copper using N.D._{max} 3 amperes. The modified form reduced this time to two and a half hours.

AN IMPROVED DESIGN

Profiting by the defects and limitations of this apparatus, another was made, shown in Fig. 2. The beakers were supported in cups, but these were fixed centrally under the electrodes above, and rotated by a belt from beneath. The cups were drilled a little large and in an annular recess inside, rubber tubing was placed to grip the beakers and take care of variations in their diameters. The electrode holders were movable vertically, electric contact being made in the upper compartment. These were of clamp form, and were a marked improvement over the rigid split holders, as they accommodated themselves to the variations in the thickness of the electrodes. Besides the three electrodes formerly used, a fourth or auxiliary one was introduced, placed behind the cathode and in parallel with it. At the end of an electrolysis, before the cathode was raised from its electrolyte, the auxiliary electrode was lowered into the solution. In this way none of the cells in the series were short circuited by the removal of the cathode, and current passed to it as long as it was in the electrolyte.

Good deposits of copper were obtained with as high as N.D._{max} 8 amperes, and 1 g. plated in $1\frac{1}{2}$ hours. Rotating speeds up to about 200 per min. were practical; above this the flat cathode acted too much as a baffle, and splattered the solution out of the beaker. With

FIG. 1. THE EXPERIMENTAL DESIGN

reference to it having been tried was found in Smith's "Electro-Analysis." In mentioning the work performed by Klobukow (1886), one of the earliest investigators in rapid electro analysis, Smith states: "In his efforts to contrive mechanical devices, he rotated the cathode, and then the anode; indeed, he even held the electrodes stationary while moving the electrolyte." Before experiments were begun to ascertain the suitability of the new method of securing agitation, it was felt that, provided it was efficient, little would be gained unless simple and convenient apparatus could be designed to apply it in everyday use.

In the assaying laboratories of the Department of Mining Engineering at the University of Toronto, the "Guess Haultain electrolytic outfit" (*Trans., A. I. M. E.* Vol. 36) is used. It seemed that the rotating beaker idea could be successfully applied to this design, thereby retaining its best features, with the added advantage of speed.

EXPERIMENTAL DESIGN

The apparatus was modified as in Fig. 1. Here three electrodes per cell were used, the cells being in series. A belt moving over the idlers provided means of revolving the upper parts of the stands, on which the

FIG. 2. THE APPARATUS IMPROVED

*Lecturer in mining engineering, University of Toronto.

the higher current density and higher rotating speed used here, it was expected that plating would be more rapid. It was noted that the plating was much heavier at the sides of the cathode than at the center; its whole area was not efficiently used. This was probably because the agitation in the beaker was more complete away from the central zone of the solution. The experiments showed that the flat form of electrode was not adapted to the method of agitation used. Cylindrical gauze cathodes were tried and found to be particularly adapted to the rotating beaker idea. Their use eliminated the necessity of a third electrode, as one anode placed in the center was sufficient. High rotating speeds could be used without the ill effects previously mentioned and uniform plating over the whole surface obtained. The apparatus would do excellent work in the hands of a sympathetic operator, but was not sufficiently practical for general use.

DESCRIPTION OF FINAL DESIGN

The final form of apparatus developed is shown in Fig. 3. Here many features have been incorporated to simplify the operation of rapid plating devices. The chief features which distinguish this from others, besides the novel method of stirring the electrolyte, are the system of wiring and the form of electrode holders. Fig. 3 shows four cell units marked A, B, C and D. A and B are in operation, C is being lowered from its electrodes, D is at rest. In the left hand compartment are housed a motor, its rheostat, a pilot lamp, ammeter, switch and two loose pulleys. A belt from the motor passes over the pulleys to the open or cell compartment, along the front and rear of four idler pulleys 1, Fig. 6, and around an end pulley. These are of aluminium with steel shafts running on a ball in the bronze bearings, supported on a cross frame. The five pulleys are

FIG. 3. FINAL FORM OF APPARATUS

spaced equidistant from the units in front. Four perpendicular wooden guide posts 2, see Fig. 6, attached to the base of the cabinet, are bored longitudinally and open to the front in a narrow slot 3. On each side of this slot are fastened upper and lower aluminium face plates 4 and 5. In the hole of the guide posts are long hollow cylindrical bearing tubes 6, of aluminium. From the lower part of these a threaded rod 7 extends forward through slot 3. On each rod in order from the face plate are an aluminium washer 8, known as the sliding contact, a rubber washer 9, and a nut 10. The bearing tubes are movable up and down the guide posts,

and are held in any desired position by the tension of the rubber as adjusted by the nut. Steel spindles turning on a ball in the lower of two bearings of the tubes support the beaker cups 11, above. The cups have two rows of inwardly projecting rubber plugs, arranged to frictionally engage the beakers, thus centering them and accommodating any variations in their diameters that may occur. Above the cups are the electrode holders, one, 12, over the spindle axis or center of the beaker and one, 13, offset to the left. These are of broad clamp form, the outside jaw of each being stationary, the other movable. After passing up into the hollow

FIG. 4. DIAGRAM OF ELECTROLYSIS CIRCUIT

top of the cabinet, these turn at right angles in wooden guides. A coil spring holds the jaws together. Push buttons 14 and 15 operate the movable jaws when desired. The electrical wiring is enclosed in hollow compartments with removable lids at the base top and back of the cabinet. Fig. 4 shows the electrolysis circuit diagrammatically, beakers being shown to correspond to the beaker positions in Fig. 3. The connection to the 110-volt. d.-c. lighting circuit used, and the lamp rheostat to control the cell current, are shown in Fig. 5, a rear view of the apparatus.

OPERATION

To follow the operation of the apparatus assume that the cups are in the lower position, as is cup D of Fig. 3. Beakers ready for electrolysis are in the cups, electrodes are in position, the belt is in motion at the desired speed as controlled by the motor rheostat. The current adjusted by the lamp rheostat will pass across the lower face plates through the sliding contacts. To operate any cell, it is raised by lifting the sliding contact nut until the electrodes are immersed in the electrolyte. On the way up, the cone face of the cup engages the belt and rotation begins. At the moment the sliding contact passes from the lower to the upper face plates, which are insulated, the electrodes will have met the electrolyte, current then passes through the cell. Any other cell may be put in operation similarly.

To terminate electrolysis on any cell, it is lowered to the starting position. The operator, with a beaker of wash water in one hand, lowers the sliding contact with the other hand, as shown in Fig. 6, transferring the water to the plated electrode quickly. The electrode is disengaged by pressing its button. While the cell is being lowered the current continues to pass through the electrolyte until the moment the solution leaves the elec-

FIG. 5. CONNECTION TO LIGHTING CIRCUIT, AND LAMP RHEOSTAT

trodes, when the sliding contact has engaged the lower face plates. Then the current passes through the lower circuit of the cell. Thus the current is not broken in other cells that may be in operation, they are protected from resolution, and current is on the electrode being removed as long as it is in contact with its electrolyte. The procedure is extremely simple, convenient, speedy and positive.

The usual manner of fastening electrodes to their holders is by screws, chucks, slots and similar devices. Some of these are ruinous to the platinum ware that is used, and are difficult to clean when attacked by vapors from the electrolyte. They often do not give sufficient area of contact, causing burning of the electrode and consequent loss in weight. The contact area of the holders here is broad and smooth. The tension on the springs is adjusted so that while firm hold is exerted on the electrodes, it is not sufficient to injure them in any way. The faces are easily accessible for any cleaning that may be necessary, so that a perfect contact is assured. The push buttons provide an easy and quick way of inserting the electrodes and removing them. The set of four cathodes may be easily removed, rinsed in two changes of water, then two of alcohol, and set to dry, hanging over the lamps of the rheostat, in eighty seconds.

The apparatus runs very smoothly, requiring a minimum of attention from the operator. The ammeter and motor, being housed in a separate compartment, are amply protected from fumes and dust, and aluminium has been utilized wherever practicable in the exposed metal parts. The $\frac{1}{2}$ -hp. motor used would operate many more units, so little power is required for rotation. It is balanced on a hinge underneath, thus accommodating itself to any changes occurring in the belt position when units are started or stopped.

TESTS FOR SPEED AND ACCURACY

In order to ascertain the speed of plating and the accuracy of the work, a number of analyses were made on copper solutions of known strength, and on unknown brasses. In order to determine the copper content of the copper wire used to make up the known solutions, duplicate analyses by electrolysis were made with gauze electrodes and still electrolyte. The method followed was that given by Heath in his "Copper Analyses," for "The

Standard Five-Gram Electrolytic Assay." These gave 4.9906 and 4.9903 g., or 99.81 per cent copper.

The known solutions were made as follows: About 20 g. of the wire were carefully weighed, heated on a water bath with 40 cc. nitric acid, 40 cc. sulphuric acid and 100 cc. of water, until all the wire was in solution and nitrous fumes were driven off. When cool, the cover glasses and sides were washed down and the solution diluted to one liter at 15 deg. C. For the tests aliquot parts of 50 cc. were pipetted at once, using a pipette agreeing with the flask and transferred to the electrolysis beakers. Fifteen cc. of a saturated solution of potassium nitrate and 25 cc. of water were added, making 90 cc. of solution. This volume filled the beakers (new form, tall Fry) over half full, leaving over 1 in. clear at the top.

On several occasions while working with other apparatus it was observed that when higher current densities and an electrolyte containing nitric acid were used, the copper deposit actually dissolved off the cathode, while current was flowing, faster than the current flowing could plate it. In order to overcome this and retain the same character of deposit obtained at lower current densities, an equivalent amount of potassium nitrate was substituted for most of the nitric acid. When this was done the deposits were satiny, pink and adherent.

Cylindrical cathodes, 2 in. high and $1\frac{1}{2}$ in. diameter, of 28-mesh, 28-gage copper gauze, were used. The stems were No. 16 copper wire, pushed through the top and bottom of the narrow lap of the gauze, the bottom end was turned back over the gauze and pressed to it. The upper ends of the stems were formed into an open loop, about $\frac{1}{2}$ in. in diameter. These afforded large

FIG. 6. OPERATOR TERMINATING ELECTROLYSIS

area of contact with the holders, and were easily hung over the lamps for drying after being washed. These cathodes are cheap, simply and quickly made, and with the exception of requiring cleaning in bright dip at least every second plating, are very satisfactory.

The immersion area was calculated to be about 100 sq.cm. This particular gauze was adopted after a series of experiments with various sizes and mesh had shown that this was the best, having sufficient rigidity, convenient weight (about 12 g.), and withstood the cleaning operations better than the others. For anodes strips of platinum foil 0.2 in. wide and 0.001 in. thick were used.

Speeds of rotation of about 500 per min. were used. As the tops of the gauze electrodes are set at the level of the electrolyte, any tendency to mount up the sides is counteracted and no splattering or throwing of the solution occurs. Table I gives the results of tests using 3 amp. current and a voltage drop of 3.7 per cell.

TABLE I

Time, Min.	Copper Deposited, Grams	Copper in Solution, Grams	Temperature of Electrolyte, Deg. C.
0	0.0000	0.9981	19
5	0.3231	0.6750	23
10	0.6252	0.3729

34	0.9982	0.0001	
35	0.9980	0.0001	40
36	0.9981	0.0000	
40	0.9980	0.0001	
50	0.9981	0.0000	
60	0.9981	0.0000	

To confirm the completeness of deposition as indicated by weighing, the depleted electrolytes were tested colorimetrically with a saturated solution of hydrogen sulphide water, against equal volumes of solution of the same acid concentration as the electrolyte, and containing 0.002 per cent copper. The usual spot plate test was found to be not sufficiently delicate. Tests after 34 min. plating time showed complete deposition of copper, though not indicated by the balance sensitive to 0.00005 milligram. The first wash waters were similarly tested, and in no case where complete deposition was indicated by the balance was any copper found in them.

Table II gives the results using 6 amp. current and voltage per cell of 4.1, also at 9 amp. and 4.9 volts.

TABLE II

Ampères	Time Min.	Copper Deposited, Grams	Copper in Solution Grams	Temperature of Electrolyte, Deg. C.
6	0	0.0000	0.9984	19
	5	0.6235	0.3759	
	10	0.9372	0.0612	
	15	0.9960	0.0024	51
	21	0.9977	0.0007	57
	25	0.9982	0.0002	
	26	0.9984	0.0000	
	30	0.9984	0.0000	63
	35	0.9983	0.0001	67
	0	0.0000	0.9984	19
9	15	0.9983	0.0001	
	16	0.9985	0.0001	
	17	0.9984	0.0000	71

The deposits of copper without exception were a beautiful pink, satiny, adherent, and firm. These tests show the capability of the apparatus in rapidly plating these large amounts of copper quantitatively, showing that with 3, 6 and 9 amperes the amounts taken are plated in approximately 35, 26 and 16 min., respectively, within very close limits of experimental error. The curves in Fig. 7 show the results plotted from Tables I and II.

This apparatus is ideal for plating the copper of brasses and alloys, allowing of assured deposition on 1 g. in 40 min. with 4 amperes, though 30 min. is usually sufficient. Unknown brasses A, B, and C were analyzed for copper. To overcome the difficulty of selecting representative 1-g. samples, 10 g. were taken, treated with 25 cc. nitric acid and water 75 cc. to end of brown fumes, 35 cc. sulphuric acid was added and heated until

FIG. 7. CURVES SHOWING RESULTS AT DIFFERENT CURRENTS

all the copper was in solution, diluted, filtered and filter washed. The filtrate and washings were brought up to 500 cc. with water; 50 cc. aliquots pipetted, 15 cc. potassium nitrate and 25 cc. water were added in beaker. Electrolysis was continued 40 min. with 4 amp. current. Table III gives the results of the work on brasses, also the results on the same brasses by other operators on this and other stirred electrolyte apparatus.

The apparatus has been thoroughly tested in two laboratories of this university, and has been subjected to the rigors of constant use in a commercial laboratory for over a year, working on the determination of copper and lead in alloys and ores, where it has given excellent satisfaction in every respect.

SUMMARY

Electro-analytical methods using still and stirred electrolytes are discussed.

Results of experimental work with apparatus employing both principles are given and explained.

An apparatus of new design, exhibiting a new method of agitating the electrolyte (stirring by rotating the containing beaker) is described, together with preliminary apparatus leading to the adaption of the apparatus in its final form.

The operation of the apparatus and the method of carrying out an analysis are given in detail.

Tests carried out with the view of determining the accuracy and speed of the new apparatus are described and results tabulated.

A table showing results of experiments on three different brasses, obtained by this and other methods of stirring and carried out by different operators, is included.

In conclusion the writer wishes to express acknowledgment of his appreciation for many helpful suggestions from the staff of the Department of Mining Engineering and to Mr. J. T. Burt-Gerrans of the Electrochemical Department for data furnished, and tests made.

American Zinc Institute Meeting

DURING the war, zinc production was stimulated to such an extent that, at the present time, the producing capacity is much in excess of the normal demand. In view of this condition, it is not surprising to find the attention of the members of the American Zinc Institute centered upon the development of new uses for zinc.

At the annual convention of the Institute held at St. Louis on June 9 and 10, George C. Stone, of the New Jersey Zinc Co., presented a summary of the advantages offered by sheet zinc for building work, roofing, gutters, leaders, flashing, cornices and other architectural materials. This field appears to be the most promising outlet for large tonnage surplus. The Institute was urged to start an educational campaign similar to that carried out by the Vieille Montagne Co., which resulted in the recognition of the value of sheet zinc in Europe. In endeavoring to find new uses for zinc, it must be remembered that this metal possesses certain limiting qualities, such as: its low strength, high thermal expansion (about double that of iron), the tendency of wrought zinc to recrystallize and become brittle at relatively low temperatures, also that it is attacked by both acids and alkalis and it can be ignited at a much lower temperature than any of the other common metals.

OTHER SPEAKERS

The subject was discussed further by E. H. Wolff, of the Illinois Zinc Co., and George S. Harney, of the American Zinc Products Co. Mr. Wolff emphasized the fact that the durability of zinc roofs is not generally appreciated by architects. Mr. Harney urged the elimination of such misnomers as spelter, jack, galvanizing and sheradizing and the substitution of terms containing the word zinc. As a result, a recommendation that "zinc" be substituted for "spelter" in all quotations, specifications and contracts and also "zinc plate" for "galvanized iron," was passed unanimously. Provision was also made for the appointment of a publicity committee to request the Government statisticians, trade journals, the Associated Press and newspapers to make these substitutions in their reports.

The presentation of these papers was followed by a lively discussion on the part of the other members of

the Institute, and resulted in the board of directors setting aside a considerable amount of money to advance this work. In this connection the plans of Dr. John Johnston, who during the war was an active member of the National Research Council, were referred to the proper committee for a prompt report to the board of directors.

ANNUAL DINNER

The annual dinner at the Hotel Statler was largely attended. Dr. W. F. Gephart, dean of finance and economics at Washington University, St. Louis, acted as toastmaster, and Edward Gengenbach, industrial commissioner of the St. Louis Chamber of Commerce, spoke on "Confidence and Progress." Pope Yeatman, at whose suggestion the Institute was formed, journeyed from New York to St. Louis to meet his old friends in the zinc world, and to talk to them on the "Influences of the War on the Zinc Industry." The speeches of the evening dealt with present and future conditions in the business world, the dominant note being "Forward, March!" The members voted to ask George C. Stone to make, in person, in the interests of the Institute, a survey of zinc conditions in Europe. Mr. Stone expects to sail early in July.

INTERESTING PAPERS READ

Among the other interesting papers read at the meetings were the following: "Some Causes of the Unsound Economic Position of the Zinc Industry in the United States," by William A. Ogg, president American Zinc, Lead & Smelting Co.; "Tri-State Mining and Production," by Otto Ruhl, C.E., Joplin, Mo.; "Mining and Production in Wisconsin," by A. M. Plumb, Wisconsin Zinc Co.; "Production of Zinc in the Southeastern States," by J. N. Houser, vice-president American Zinc, Lead & Smelting Co.; "Early Days of the Industry," by C. E. Siebenthal, of the U. S. Geological Survey; "Mines Taxation," by R. C. Allen, director, Geological and Biological Survey, Michigan. An interesting moving picture lecture on "Safety Lessons in Metal Mining" was given by B. F. Tillson at the close of the Monday meeting. The badges worn by members were made of zinc and a diversified exhibit of new uses for zinc was displayed at the unique registration booth of the Institute in the corridor of the Hotel Statler.

A budget of \$20,000 to forward the aims of the Institute was approved by the members, which now number nearly 200, and the following officers and directors were elected:

OFFICERS

Term expiring 1920: President, Charles T. Orr; first vice president, Edgar Palmer; second vice president, James L. Bruce; third vice president, F. C. Wallower; treasurer, Howard I. Young; secretary, Stephen S. Tuthill.

BOARD OF DIRECTORS

Term expiring 1920: George O. Argall, Joseph Brennemann, Arthur Thacher, C. M. Loeb, Edward M. Mellvain, George E. Nicholson, F. C. Wallower; term expiring 1921: J. H. Billingsley, P. B. Butler, Julius W. Hegeler, Cornelius F. Kelley, William A. Ogg, Edgar Palmer, O. S. Picher; term expiring 1922: James L. Bruce, A. P. Cobb, A. S. McMillan, Charles T. Orr, Victor Rakowsky, Wm. F. Rossman, E. H. Wolff.

The next meeting of the Institute will be held in Chicago on the second Monday in May, 1920.

Treatment of Complex Speisses*

Description of Recent Research on the Treatment of Complex Speisses and the Application of the Results to Commercial Metallurgical Processes—Proposed Method of Treating With Pyrites in an Electric Furnace

By PAUL PAPENCORDT

Translated by Oliver C. Ralston

AMONG the many intermediate products obtained in metallurgy which make it difficult to prepare pure metals direct from the ores, the speisses are perhaps the most troublesome because the recovery of the valuable metals from them is attended with unusual difficulty. It is not many years since speisses were discarded even by large smelters. In those smelters where speisses are treated the methods are tedious and often expensive. The purpose of this work was to devise a simpler process not subject to the excessive losses now suffered by smelters.

The speiss on which the tests were made came from the copper smelter at Oker-a-H. Its composition was as follows:

	Per Cent.		Per Cent.
Cu...	23.50	Ni+Co...	2.90
Pb...	16.30	Zn...	3.10
As...	12.20	S...	2.10
Sb...	13.20	Au+Ag...	0.12
Fe...	26.20		

Just how far the constituents of such a complex are chemically united and how much they are in solution in each other is difficult to determine. Among the binary systems of various elements with arsenic or antimony which have been studied we find the following described by Friedrichs in the volumes of *Metallurgie* from 1905 to 1908:

In the system copper-arsenic there are two chemical compounds, Cu_3As and Cu_4As . However, the arsenic is only loosely bound in the copper-arsenic alloys. Alloys high in arsenic lose most of it by merely standing in powdered form in a space heated to 300 deg. C. or higher.

In the system iron-arsenic the following compounds are found: Fe_3As , Fe_2As , and apparently FeAs . The compound Fe_3As forms a eutectic with arsenic which freezes at about 830 deg. C., but it forms mixed crystals with Fe_2As , if cooled quickly. The compound Fe_2As is the product of a reaction which takes place at about 800 deg.

In the system nickel-arsenic there are two compounds, NiAs and Ni_2As . The existence of NiAs is well proved, but that of Ni_2As is doubtful. Nickel-arsenic alloys have not hitherto been roasted and refined with much success.

In the system iron-antimony are two compounds,

Sb_2Fe_3 and Sb_2Fe . In the system cobalt-arsenic are Co_2As_3 , Co_2As and Co_3As_2 .

The main object to be obtained is to eliminate the arsenic and antimony from these speisses. In practice this is done by roasting either the molten or non-molten material, and a strong blast of air is passed either through or over it so that more or less of the arsenic and antimony are removed as volatile oxides. For instance, the process used at the copper smelter in Oker-am-Harz consisted in treating speiss in the so-called speiss-furnace by the "blast-process." This furnace had water-cooled top and bottom. The side walls, arch, fire-bridge and flue gas ports were of firebrick. The hearth was built in three layers. On the iron bottom was laid a layer of tamped marl covered with the layer of firebrick. This was made of a mixture of 20 parts of slate splinters with 80 parts of crushed marl. The furnace was fired by simple reverberatory firing with under-draft. The excess air for oxidation was led in through two nozzles. The refining or 'blowing' process took place in the following manner: After the charge had been placed in the furnace all openings were luted shut and the temperature was raised to a glowing red. Several hours were allowed at this temperature for the roasting. Then the temperature was raised suddenly, compressed air turned on and the charge allowed to melt and the dross to separate. First the iron oxides and slags with the hearth; then the antimony and lead oxidize and enter the iron silicate slag, making it very basic. The greater portion of the arsenic can be volatilized only after these elements have been slagged, and during this stage the temperature of the furnace can be so lowered that the contents of the furnace become quite pasty. The removal of the arsenic is indicated by the cessation of fumes, after which the firing is increased again and the concentration of the speiss has been accomplished.

ANOTHER PROCESS

Another interesting process for the working of speisses is given by Guillemin in *Metallurgie*, 1910, 598. Here the speiss-bath was blown with dry chlorine gas. The antimony and arsenic were removed very well, but the process proved too expensive. Guillemin later directed his attention to cheapening the ordinary de-arsenification methods. He used blast-roasting methods similar to those used in the Savelsberg and the Huntington-Heberlein processes for lead ores. The ground speiss was mixed with difficultly-fusible material like limestone, or acid slag, and either preheated before placing in the blast pots or only partially heated before filling the pots in the regular manner. By blowing to a glowing red most of the arsenic and antimony volatilized as As_2O_3 and Sb_2O_3 .

*Translated from *Metall und Erz*, 16: 6-13 (1919). This paper was given as a communication from the Institut für Metallhüttenwesen und Elektrometallurgie der Kgl. Techn. Hochschule Aachen, and gives the results of some tests on the treatment of complex speisses which could only be carried out on a small scale, due to war conditions. The suggestions embodied in the paper have great promise of solving more satisfactorily the treatment of such undesirable complexes as are met in the speisses of some copper smelters. Pure arsenic sulphide is sold as a rather expensive pigment which has mostly been produced in Germany until war conditions shut off the supply. If any German smelters start using this method of working up their complex speisses they will be able to undersell manufacturers of arsenic sulphide as it is made at present in the United States.—[TRANSLATOR.]

All of these processes give a mixture of metal oxides which are by no means free of sulphides of arsenic and antimony. A glance at the voluminous literature on beneficiation of such products is sufficient to show that the treatment of these mixtures is attended with great difficulties. No process has ever been in the least satisfactory. The process of Schilowski, developed at the Institut für Metallhüttenkunde und Elektrometallurgie der Königliche Technischen Hochschule zu Aachen, (see *Metallurgie*, 8, 617, 1911), for electric smelting of copper ores containing arsenic, seemed to offer the best chances of success. In this process the arsenic was completely volatilized as a sulphide and condensed in a small condenser. As to whether antimony could be similarly removed, only tests could tell.

These tests relied on electric melting with exclusion of all air combustion gases. The melting of the speiss was performed in a graphite crucible into which projected two carbon electrodes, forming an arc furnace (see Fig. 1). A hole was bored into the bottom of the

FIG. 1. FURNACE IN WHICH TESTS WERE MADE

crucible and a carbon electrode fitted in, while the others were introduced through corresponding holes in the cover. The bottom of the crucible was covered with tar and the side was fitted with a suitable delivery tube leading into an iron box condenser which was divided into a number of compartments. This box served to condense the sublimed products and the opposite end was connected to a ventilating chimney to dispose of any gases.

The speiss contained only 2.1 per cent sulphur, and it was therefore necessary to add enough to form sulphides with the arsenic and antimony. Pyrite seemed to be the best addition agent. A sample of pyrite containing 35.1 per cent sulphide was used. In order to convert the other metals into sulphides it was necessary to add the following amounts:

	Per Cent.		Per Cent
Pb into Cu_2S	6.0	Co-Ni into $(\text{CoNi})_2\text{S}$	1.5
Pb into PbS	2.0	Zn into ZnS	5.0
As into As_2S_3	7.5		
Sb into Sb_2S_3	5.0	Total	38.5
Fe into FeS	15.0		

Since the speiss contained 2.1 per cent sulphur, 36.4 per cent sulphur had to be added. In these tests, therefore, the speiss and pyrite were both powdered and mixed and then melted together in the furnace, with exclusion of air. Each test took 20 minutes.

TEST 1

A charge of 1 kg. speiss with 0.5 kg. pyrite was melted. In a very few minutes after turning on the current brown fumes poured out of the outlet of the condenser. The color and smell indicated arsenic sulphide. The evolution of the arsenic sulphide was so fast that the

condenser proved to be too small for complete condensation of the arsenic sulphide.

The results of this test were: a speiss which had settled to the bottom; copper matte, a glassy slag and a sublimate. Analysis gave:

Matte:	Per Cent	Antimonial Speiss	Per Cent
As	0.11	As	0.27
Cu	25.8	Cu	7.96
Sb	0.15	Sb	17.94

Copper Balance
Charge contained: 1000 g. speiss with 23.5 Per Cent Cu = 235 g. Cu

Products contained:			
685 g. matte with 25.8 Per Cent Cu	=	176 g.	= 74.89 Per Cent
725 g. speiss with 7.96 Per Cent Cu	=	57.7 g.	= 24.57 Per Cent
220 g. slag with 0.17 Per Cent Cu	=	0.4 g.	= 0.15 Per Cent
Loss	=	0.9 g.	= 0.39 Per Cent
Total	=	335 g.	

TEST 2

In this case 1 kg. of speiss was melted with 1 kg. of pyrite in the same manner as in Test No. 1, and enough sulphur was present to convert all the metals into sulphides. It lasted 20 min. and the products again were matte, speiss, slag and sublimate.

Matte:	Per Cent	Speiss	Per Cent
As	0.0	As	0.08
Cu	26.2	Cu	3.66
Sb	0.03	Sb	16.52

Copper Balance
Charge contained: 1000 g. speiss with 23.5 Per Cent Cu = 235 g. Cu

Products contained:			
780 g. matte with 26.2 Per Cent Cu	=	204.36 g.	= 86.96 Per Cent
790 g. speiss with 3.66 Per Cent Cu	=	28.82 g.	= 12.22 Per Cent
250 g. slag with 0.21 Per Cent Cu	=	0.52 g.	= 0.27 Per Cent
Loss	=	1.3 g.	= 0.55 Per Cent
Total	=	235 g.	

TEST 3

In this test 1 kg. of speiss was melted with 1.5 kg. of pyrite, meaning an excess of sulphur, but again there were matte, speiss, slag and sublimate.

Matte:	Per Cent	Speiss	Per Cent
As	0.0	As	0.02
Cu	28.3	Cu	4.15
Sb	0.031	Sb	16.6

Copper Balance
Charge contained: 1000 g. speiss with 23.5 per cent Cu = 235 g. Cu

Products contained:			
710 g. matte with 28.3 Per Cent Cu	=	200.93 g.	= 85.15 Per Cent
780 g. speiss with 4.15 Per Cent Cu	=	32.37 g.	= 13.70 Per Cent
280 g. slag with 0.23 Per Cent Cu	=	0.60 g.	= 0.20 Per Cent
Loss	=	1.10 g.	= 0.40 Per Cent
Total	=	235 g.	

From these three tests it could be seen that in all three cases there was obtained a copper matte containing only traces of arsenic, a speiss free of arsenic but rich in antimony, a slag and a sublimate. Also most of the copper could be converted into a matte. A small amount of arsenic in the matte of Test 1 was due to deficiency of sulphur. Still the matte contained on an average 85 per cent of the copper and the remainder insisted on staying in the antimony speiss. In the speiss nearly all of the original antimony was present. This was confirmed by analysis of the sublimate.

Four more tests were made to see if a longer time in the furnace would cause the antimony to volatilize as Sb_2S_3 . Test 4 lasted 25 min., Test 5 lasted 30 min., Test 6 lasted 40 min. and Test 7 lasted 50 min. The results scarcely varied from those already reported.

CONCLUSIONS

It therefore seemed safe to conclude that by melting a speiss in an electric furnace with pyrite and with exclusion of air there can be obtained:

- Copper matte, free from arsenic, containing most of the Cu.

- (b) Antimony speiss, free from arsenic, containing the remaining Cu.
- (c) Barren slag.
- (d) Arsenic sulphide sublimate.

The arsenic of the original speiss was almost completely volatilized, while the antimony was almost completely recovered in the new speiss. That most of the arsenic was also in the sublimate was later confirmed by analysis, and it also contained very little antimony. Most of the original speiss had been converted into a leady copper matte, the subsequent treatment of which will be mentioned later.

TESTS ON THE NEW SPEISS

The new speiss still contained enough copper to make another operation for the recovery of this copper necessary. It is well known that antimony sulphide is soluble in water solutions of alkali sulphides forming sulphantimonates. The new speiss was pulverized, mixed with coal and sodium sulphate and heated in a Helberger crucible furnace in order to convert the antimony of the speiss into sodium sulphantimonate. The reaction is:

The fused mass was allowed to cool, pulverized and leached with hot water in a rotating glass barrel which was kept heated by bunsen burners. The results of the tests were as follows:

Test	Speiss Leached	Time, Hr	Water, cc	Antimony Dissolved, g.	Per Cent
1	100	1	1000	12.13	73.00
2	100	2	1000	14.78	89.00
3	100	3	1000	16.43	99.45
4	100	4	1000	16.45	99.58
5	100	5	1000	16.48	99.75

These tests showed that the leaching of practically all of the antimony took place in 3 hr. and that only traces were extracted by longer leaching. The residue contained the copper, lead and iron as sulphides, together with the precious metals, and could be combined with the copper matte to be treated by standard methods. The fact that the antimony in the speiss was soluble in water as Na_3SbS_3 makes it possible to isolate it as a by-product which can be converted either into antimony pigments or into metal. Some iron sulphide seems to dissolve, imparting a turbidity to the solution. Metallic antimony can easily be obtained by electrolysis of this solution.

To test this latter process an accumulator jar was used for electrolytic bath with lead sheet anodes and sheet iron cathodes. A tension of 2 v. was used, and in order to prevent precipitation of iron with the antimony some common salt was added to the electrolyte. At the end of the electrolysis the antimony was present on the cathodes as gleaming plates. The solution electrolyzed originally contained 8.21 g. of antimony and the weight of deposited metal was 8.21 g. Hence the loss of antimony is very small, and the earlier work of Borchers (Lehrbuch der Elektrometallurgie) has shown that the electrolysis is very simple.

TREATMENT OF THE SUBLIMATE

In these tests the sublimate from the original Test 2 was used. In this test 210 g. of sublimate with an arsenic content of 45.3 per cent had been obtained, and it was also found that it contained 0.47 per cent Cu. The original charge of 1 kg. speiss had contained 121 g. arsenic, and the 210 g. of sublimate contained only 95.13 g., showing that 25.87 g. had been lost. This corre-

sponded to a recovery of 78 per cent. The arsenic was present as As_2S_3 and in order to be obtained pure from sulphides of copper, iron, lead and zinc it had to be resublimed at a temperature of 700 deg. C.

A lot of 50 g. was heated between 700 and 800 deg. with exclusion of air and a brown vapor passed over into a water-cooled condenser. The 50 g. of material tested contained 22.6 g. arsenic and the sublimate contained 35.2 g. with 59.8 per cent As, or 20.79 g. arsenic, meaning a recovery of 92 per cent of the arsenic. This was done in a carbon crucible and there remained a residue of copper, nickel, iron and arsenic. This residue could be treated with the original speiss in practice.

Analysis showed that the resublimed arsenic contained no impurities except some free sulphur. In practice such a pure product might be difficult to obtain with a single resublimation, but it could be resublimed.

TREATMENT OF THE COPPER MATTE

The arsenic-free copper matte contained a great deal of lead as well as some nickel and cobalt, and the same was true of the residue from the antimony leaching. Rauschenplat has shown (*Metallurgie* 7:154, 1910) that the lead can be slagged away from the copper very easily by forming a siliceous slag. Therefore part of the matte was pulverized, mixed with silica and dead-roasted in a muffle until sintering commenced. This was then mixed with some unroasted matte and more silica and melted in an electric furnace, sketched in Fig. 2, to allow the reaction process to take place.

FIG. 2. ELECTRIC FURNACE IN WHICH THE COPPER MATTE IS TREATED

The result was a black copper metal containing the precious metals and nearly all of the nickel and cobalt, while the slag contained the iron and practically all of the lead in the form of silicates. The copper contained 92.4 per cent Cu, 6.7 per cent Ni and Co, and 0.25 per cent Fe. This product can enter the commercial copper-refining processes, especially the electrolytic refining process, which recovers all the metals mentioned. No tests were made, since it is known that it is possible to make cathode copper, anode slime containing the precious metals, and the nickel and cobalt enter the electrolyte. The lead silicate slag can also be treated by the roast-reduction process to form work-lead, a process which is standardized.

SUMMARY

The method of treatment of the speiss will therefore be: Melting in the absence of air and with the addition of pyrite in an electric furnace, whereby the volatile products can be conducted away and condensed. The products obtained are:

1. Arsenic-free copper matte with traces of antimony, but containing at least 80 per cent of the copper con-

tent of the speiss. The copper content of the matte amounts to 25 per cent.

2. Antimonial speiss with traces of arsenic and up to 4 per cent Cu, which amounts to about 20 per cent of the total copper content of the original speiss.

3. Sublimate, consisting essentially of arsenic sulphide but contaminated with small amounts of sulphides of copper, iron, lead and zinc.

The copper matte is mixed with silica and dead-roasted, followed by smelting with unroasted matte, giving copper metal which contains the precious metals and the nickel and cobalt.

The antimonial speiss is powdered, mixed with sodium sulphate and coal and melted. The melt is leached with hot water to form a solution of Na_2SbS_3 and the residue, containing copper, lead, nickel and cobalt sulphides with traces of precious metals, is worked up with the copper matte. Metallic antimony is thrown out of the solution by electrolysis.

The sublimate is resublimed at about 700 deg. C. forming arsenic sulphide, which finds direct commercial application. Nearly all other processes of treating speisses do not recover the arsenic and antimony in the form of easily marketed by-products.

COMMERCIAL APPLICATION OF THE NEW PROCESS

It is now possible to outline the fundamentals of a new metallurgical treatment of speisses. The proposal was to melt speisses with pyrite in an electric furnace, but in practice it would be more profitable to use cupriferous pyrite or pyrite containing precious metals. Only a carbon-lined electric furnace seems proper for the melting and in order to prevent the corrosive action of the molten speiss it would be best to water-cool the bottom and the bottom third of the side walls. Since metallurgical speisses are ordinarily formed in a molten state, they should be collected in a fore-hearth in the copper smelter and then fed into the electric furnace in the molten state. Here the pyrite is added in the calculated proportion, the furnace closed air tight and the current of electricity passed for a time. Only a small energy consumption need be met in the furnace and the only doubtful point is whether the pyrite and speiss get thoroughly mixed. The liquid contents of the electric furnace are then tapped out.

The new antimonial speiss, by virtue of its high specific gravity, is found on the bottom of the furnace and is tapped first. It is ground, mixed with sodium sulphate and coke, and placed in a preheated smelting furnace, whereby the antimony is converted into sodium sulphantimoniate. The contents of the crucibles are poured out. Any floating matte is removed and worked up later. The melt is cooled and pulverized and leached with hot water.

Leaching apparatus should consist of iron vats with conical bottoms and steam inlets to warm and stir their contents. Other settling tanks are needed and slime-filters to separate the solution from the residue of copper, lead, iron, etc. The solution should be electrolyzed according to Borchers' process. (See Borchers' "Elektrometallurgie.")

The antimony electrolysis installation should consist of a series of vats in cascade. The baths will be rectangular iron vessels in which are hung alternately sheets of lead and of iron as anodes and cathodes. The vessel also forms a cathode. Since the solution becomes specifically lighter during electrolysis, the liquor must flow

into the bottom of each cell and overflow from the top. The current density must fall with the antimony content of the solution. About 100-150 amp. per sq.m. is all right at the beginning, but toward the end only 40-50 amp. per sq.m. can be used. This can be done by building baths progressively longer. The antimony scales or powder stick in part to the iron cathodes and part falls to the bottom of the cells. Since the solution contains some iron, the deposited antimony contains some iron, and this must be removed during the melting of the antimony by adding antimony sulphides to the metal or by adding some common salt. The leach liquor is oxidized by air and concentrated until sodium hyposulphite crystallizes out. This is an article having a wide market.

Passing to the treatment of the crude sublimate, it was found that the red color was due to the presence of As_2S_3 , and in separating from the other metal sulphides it is necessary to resublime it in a Freiburger subliming furnace. This consists of three tiers of 12 clay retorts, each of which are about 1.5 m. long and 12 cm. in diameter (4.5 ft. x 5 in.). The material is introduced into the back ends of the retorts, and these are heated to a dull red glow. After carrying out the sublimation the residue is taken out and added to the next charge of speiss that is melted in the electric furnace with pyrite. The sublimate which collects in the condenser is the arsenic sulphide of commerce.

The treatment of the copper matte should be as follows: The matte is pulverized, mixed with the cupriferous residue of the antimony leaching and with silica, and roasted either in a stationary furnace or a revolving roasting furnace. The temperature will be held at such a point that incipient sintering takes place. The roasted material is then mixed with unroasted matte in the proper proportion and treated in a shaft furnace, forming metallic copper containing cobalt, nickel and the precious metals. This is an article of commerce, or it can be electrolytically refined. The lead from the matte passes into a silicate slag from which it can be smelted by standard processes, forming work-lead.

Spelter Production in United States

The Department of the Interior, by the United States Geological Survey, reports as follows on spelter produced in the United States, during 1917-18.

Manufacturing Plant of the Providence Gas Co.—I

Review of the Development of the Gas Industry in Providence, R. I.—Description of the Plant as It Was Before the Installation of the Koppers Combination Gas Ovens

BY WALTER M. RUSSELL*

THE City of Providence, Rhode Island, U. S. A., is located at the head of Narragansett Bay, about thirty miles from the open ocean. The city proper has an area of something over 18 sq.m. and a population within this area of about 250,000. As a seaport, it ranks tenth in the United States in bulk of tonnage and value of cargoes, having direct connection by water with Philadelphia, Baltimore, Norfolk and Mediterranean ports. It is the leading oil port of New England and with the completion of a new 30-ft. channel will have one of the best harbors in the world.

Providence is a great manufacturing city, being first in the country in the manufacture of jewelry and silverware, also having the largest mechanical tool factory, file factory, engine factory, screw factory and silver factory in the world. It is surrounded by the greatest textile districts of the country.

Gas is supplied to the city proper, also to Olneyville, cities and towns of North Providence, East Providence, Cranston, Riverside, Barrington, Warren and Bristol, serving in all about 65,000 consumers, utilizing some 450 miles of mains.

Being the center of a great industrial section and known as the "southern gateway" of New England, it is the logical point for the distribution of gas and coke to industries requiring these commodities.

The Providence Gas Co. first commenced operations in the year 1848. A coal gas works was erected on the east side of the Narragansett Bay and became known as the East Station. This gas works continued in operation until the year 1870, at which time the output of gas was about 132,000,000 cu.ft. per year.

In 1870 a new gas works was built on the west side of the Bay, called the West Station. This plant was considered a model for its time and it was in this works that some of the first recuperative benches in the United States were successfully operated. Coal gas only was made in this plant until the year 1891, when water gas sets were installed.

In 1877 the Citizens Gas Co. began operations in opposition to the Providence Gas Co. During the '70s there was a great deal of activity in the United States on the part of opposition gas companies. These were usually organized by promoters for the purpose of putting up a plant which would later have to be bought out by the established company at a profit to the promoter. As a rule, these companies put up cheap water gas plants, but in this case there was an exception, as the Citizens Gas Co. built a coal gas plant which was purchased by the Providence Gas Co. in the year 1878 and became known as the South Station. In 1890 water gas sets were built in this works. The West Station then became

known as the North Station, and these two works, the North Station and the South Station, continued in active operation, making coal and water gas, until 1911.

THE SASSAFRAS POINT STATION

Between 1900 and 1906, the output of gas increased 50 per cent and in 1905 it became evident that the capacity of these stations would soon be exceeded; also both the North and the South Station were situated where adjoining land was extremely expensive to purchase and the land already owned was so closely covered with buildings as to allow of no further expansion. It was, therefore, determined to plan for the future, and 40 acres of land were purchased situated about two miles southerly from the town, bordering on Narragansett Bay and having a railroad connection with the New York, New Haven & Hartford Railroad. During the next four years, many plans were carefully considered, which culminated in the construction of an entirely new coal gas plant at the new site, which became known as the Sassafras Point Station.

In 1910 the North Station was abandoned and the following year, with the starting of the new coal gas plant at the Sassafras Point Station, coal gas was discontinued at the South Station, it being continued only as a water gas plant. The output for the year 1910 was 1,386,819,000 cu.ft.

In January, 1909, a contract was let to the Didier-March Co. to build a retort house complete from the coal crusher to the coke storage bins; the retort house to be capable of housing four batteries of retorts, two only being built at first. These batteries each consisted of six benches, containing ten retorts, making 120 retorts in the first installation. This was followed by a third battery of 60 retorts in 1911, and in 1912 a fourth stack was built of six benches each, containing 15 retorts; so that the total capacity of the house was 270 retorts. The construction of the coal handling equipment, condensing and purifying buildings and equipment and the meter house and power house equipment was done by the Bartlett Hayward Co.

Ground was broken April 1, 1909, and the first gas was made in October, 1910. The system of coal carbonization adopted was the Dessau vertical retort slightly modified to meet American conditions. The plant as finally completed had a nominal daily capacity of 3,200,000 cu.ft., and was in operation until January, 1919, when the retorts were abandoned and a battery of 40 Koppers combination gas ovens were turned on.

ALL MANUFACTURING PLANTS COMBINED

In 1916 a new water gas plant was built at Sassafras Point and all manufacturing was abandoned at the South Station, thus bringing all the manufacturing

*Read before the American Institute of Chemical Engineers, Cambridge, Mass., June 20, 1919.

plants together at one works. In 1905 a 4,000,000-cu.ft. holder was built near the South Station. In 1911 a 6,000,000-cu.ft. holder was built at Sassafras Point and in 1915 a 3,000,000-cu.ft. holder was built in a suburb of Providence for reinforcing the supply in that district. All holders were built by the Bartlett Hayward Co. and are telescopic holders contained in steel plate tanks on concrete foundations.

During 1917 it became apparent that the vertical retort plant had reached the end of its useful life, and various plans were considered for replacing it with coal carbonizing equipment. It was finally decided to build a battery of 40 Koppers combination gas and coke ovens, which would give a nominal generating capacity of 7,000,000 cu.ft. per day, capable of making at least 10 per cent more gas than their rating, if desired. The construction of this plant was started early in 1918 and gas was first made the latter part of January, 1919.

At the present time the Providence Gas Co. is equipped with a water gas plant which can easily generate 9,000,000 cu.ft. of gas per day and with a coal plant generating up to 7,750,000 cu.ft. per day. As the present output is in the neighborhood of 2,250,000,000 annually, with a maximum daily output of 9,300,000, it would appear that no further extensions of the plant, should be necessary for years to come.

All buildings and practically all apparatus now used in generating gas were new within the last ten years and represent in every respect the most up-to-date and modern practice in the United States. It is proper to say that the Providence Gas works is the model gas plant of New England, if not of the United States.

COAL GAS WORKS OF 1910

The first plant to be erected at Sassafras Point was the Dessau vertical coal gas works, which was built under the supervision of the gas company's engineer, Mr. Carroll D. Miller, who has described the construction and operation of this plant in papers before the New England Association of Gas Engineers and also the American Gas Institute, from which papers I have liberally drawn for the information given herewith.

COAL STORAGE PLANT

A sea wall of stone masonry was constructed and has since been extended to be about 600 ft. long, and there is a depth of about 28 ft. of water at high tide, which will accommodate all ordinary coal barges and some of the large capacity steamers. For unloading coal from barges and delivering to the storage pile or storage shed, a coal bridge (Fig. 1) was erected by the Brown Hoisting Machinery Co. This coal bridge has a capacity of 100 to 150 tons per hr., depending on the conditions. Coal is picked up with a 2-ton clamshell bucket. One leg of the coal bridge runs on the sea wall, the other leg on rails close to the coal shed, with a 211-ft. span. The trolley handling the clamshell bucket has a travel of 304 ft. and the total length of the bridge is 324 ft., including overhang. The clearance of the bucket from the ground is 56 feet.

The bridge can travel in longitudinal direction 600 ft. Coal can be unloaded with this bridge from barges to the storage pile and then rehandled into the shed, or it can be handled by the bridge from barges into the shed, or it can be dropped directly into the hopper feeding the coal crushers and belts to the retort house.

At the north end of the storage ground is an open

FIG. 1. COAL BRIDGE AND COAL STORAGE HOUSE

bin of 1000 tons capacity, which is now being used for buckwheat boiler fuel. Adjacent to this is a space reserved for 10,000 tons of broken anthracite for water gas generation. The rest of the storage space is divided up between high volatile and low volatile coking coals with storage capacity of a total of about 60,000 tons.

Coal Shed—The coal storage shed was arranged to store a maximum of 8000 tons of coal under cover.

The framework of the shed is constructed of "A" steel frame bents, the bents being designed to carry the sides, roofing and tracks of the main trolley, which is used for reclaiming the coal from the storage shed and passing same into the hopper over the crusher.

The bottom of the coal shed and foundations of the steel frame are of concrete. The roof over the shed is provided with movable sections or hatchways, so that the storage bridge may deposit coal into any portion of the shed. This storage shed was originally used for gas coal for the retort house but is now used for storing bituminous coal for use in the producer gas plant. The reclaiming is done by means of Dodge telfers, having 2-cu.yd. buckets.

RETORT HOUSE

The retort house, which was built entirely by the Didier-March Co., is of German design. The building is 85 ft. wide, 215 ft. long and 59 ft. high to the ridge. The roof is open in the center to give the greatest possible ventilation, combined with louvers placed in the side walls of the house. There were also provided 28 double sliding doors to make the house easily accessible from all sides and 74 windows. A platform was constructed in front of each stack at the height of the bottom of the retorts and another platform in front of the hydraulic mains, with an operating floor around the tops of the benches. The roof was constructed of graduated reinforced asbestos sheets fastened to channel purlins with aluminum wires.

Coal Handling—A steel hopper receives the coal from the telfer or bridge, dropping it into a weighing hopper and thence the coal goes onto an apron feeder, which carries the coal to jaw crushers. From the jaw crushers, bucket elevators carry the coal to the top of the retort house. These bucket elevators have 66-ft. centers and are made up of No. 10 steel "V" shaped buckets measuring 20 in. by 50 in., driven by motors. The bucket elevators discharge onto belt conveyors having 200-ft. centers, which deliver the coal from the elevator to the coal bins. This belt is 18 inches wide

FIG. 2. TOP OF BENCHES

and is provided with a self-propelling automatic reversing tripper running on rails, which discharges the coal automatically over the entire length of the coal bin. Each of these coal bins has a capacity of 260 net tons and is constructed of steel plates properly stiffened. Each bin is provided with a series of discharging valves of the swinging undercut type. At the present time, as the retort house has been abandoned for generating coal gas, the north bin is not in use. The south bin is now used for the fuel for the producer gas plant, which furnishes the gas for heating the coke ovens.

Benches—Four stacks of vertical benches were erected, three consisting of six benches of ten retorts each, the fourth consisting of six benches of fifteen retorts each. In the benches of 10's, the retorts measure $22\frac{1}{2}$ in. by 9 in. at the top and 27 in. by 14 in. at the bottom and are 13 ft. 2 in. long. The recuperating system is located on both sides of the generators, consisting of a system of primary and secondary air flues and adjacent to a series of waste heat flues which convey the products of combustion to the lower portion of the benches. (Fig. 2.)

The generators were located on one side of the benches adjacent to the retorts and the producer gas entered the main oxide flue through two openings about 3 ft. above the grate bars. The coke charging openings are located some 14 ft. above this point on a level with the retort operating floor, this space serving for coke storage.

VAPORIZERS

A vaporizer for each generator was located underneath the ash pan and vaporization was effected by the products of combustion before entering the main smoke flue. The vapors produced were conducted under the grate and thoroughly mixed with the heated primary air. A separate main smoke flue 3 ft. square was provided for each stack connected to a chimney outside the building. Four chimneys were erected of hollow radial molded blocks of the Custodis system and are 125 ft. high with 4 ft. inside diameter at the top.

The lower mouthpieces were operated from the outside of the benches by means of a system of levels, racks and pinions. A separate hydraulic main was provided for each bench. These hydraulic mains were sealed only during charging of the retort, which was accomplished by means of a weir valve, which was raised shortly before charging time and which allowed the cir-

culating liquor to fill up and seal the dip pipes. Underneath each dip pipe was placed a pitch pan, which could easily be removed for cleaning. Two foul mains, one on each side of the house, carried gas to the end of the building and thence to the underground foul main.

CHARGING THE GENERATORS

For charging the generators with coke, a steel plate hopper was used, running on a monorail. Before charging coal into the retort, the bottom of the retort was filled with a small amount of coke breeze by means of a traveling breeze hopper. This was followed by the coal-charging hopper, which was constructed to charge two retorts simultaneously on the benches having ten retorts and three retorts on the benches having fifteen. The coke which discharged from the retorts fell into a movable chute, which brought the coal over to a De-Brower hot coke conveyor located in front of the stacks. (Fig. 3.) Originally the conveyor discharged into a skip hoist, which elevated the coke into a night storage bin, but this system was found unsatisfactory and was changed to deliver the coke into a second conveyor, which, in turn, carried the coke to concrete pits. Just outside of the retort house was a set of water sprinklers, which quenched the hot coke, the steam being carried away by a vertical flue.

The fourth stack of benches to be erected was built with fifteen retorts to the bench, which was thought to give some economies in operation. The retorts were $19\frac{1}{2}$ in. by $9\frac{3}{4}$ in. at the top and $24\frac{3}{4}$ in. by $14\frac{1}{2}$ in. at the bottom, having the same length of 13 ft. 2 in. The other constructional details were similar with the exception of the method of handling the lower mouthpieces, which were handled by hydraulic valves rather than by hand, which was an immense improvement. Also the steam vaporizers were omitted and step grates were used instead of bar grates. Step grates were also used on the third stack to be built.

The coke which was quenched by the water sprays and carried by a second chain conveyor passed over a grizzly, where a large part of the breeze dropped out, and then fell into concrete pits, whence it was handled by telfers.

A telfer system with a clearance of 54 ft. above ground level handled the coke from the pits to storage or to the screen houses. These telfers were later extended to handle coke to the water gas plant and also

FIG. 3. SIDE VIEW OF BENCHES

anthracite for the water gas plant and coke breeze or other fuel for the boiler plant and, at the time of completing the coke oven plant, they were still further extended to take care of the coke from the ovens.

The coke was handled to storage and to the shaker screen houses with 2½-ton clamshell buckets.

CONDENSING PLANT

Buildings—At the time this plant was built, it was common practice to house all condensing plants. In the past few years, the use of outdoor condensing plants has grown rapidly in favor. The condenser house is 45 ft. wide by 120 ft. long and about 30 ft. high, with brick walls carrying steel roof trusses. The roof is of terra cotta hook tile covered with slate with a monitor extending the whole length of the building, having pivoted sash. Concrete floors are provided throughout.

Condensing Equipment—The condensing plant as originally constructed consisted of two primary condensers, two exhausters, two tar extractors, two secondary condensers, two rotary ammonia scrubbers. Later a Feld washer was constructed to assist in ammonia recovery.

The primary condensers are rectangular water tube condensers, having 3200 cu.ft. effective cooling surface each. The combined capacity of these two condensers is 3,000,000 cu.ft. per day. Following the primary condensers is a duplicate installation of Connorsville exhausters, having a capacity of 17 cu.ft. per revolution, and equipped with Isbel-Porter governors. Tar extraction is provided for by two Bartlett-Hayward P. & A. tar extractors with a single submersion chamber, the shell being of cast iron. There are two of these tar extractors and each of them has a capacity of 3,000,000 cu.ft. per day.

Following the tar extractors are two secondary rectangular water tube condensers, each having an effective surface of 6000 sq.ft. (Fig. 4.) The water used on the secondary condensers passes to the primary condensers. The temperature of condensation is controlled by Tagliabue regulators.

FIG. 4. SECONDARY CONDENSERS

FIG. 5. ROTARY SCRUBBERS FOR FINAL REMOVAL OF AMMONIA

A 5-ft., 7-section Feld washer serves as a primary ammonia scrubber and has developed into a very useful apparatus, for the removal of hydrogen sulphide, in combination with ammonia in the liquor from the secondary scrubbers.

FINAL REMOVAL OF AMMONIA

The final removal of ammonia was secured by two rotary scrubbers (Fig. 5) constructed in five days, having a diameter of 10 ft. The washing surface is composed of standard wood grids, the washer being supplied with a small engine directly connected to a worm operating on the worm wheel attached to the shaft. All connections in the building are 24 in. diameter straight pipe made of steel plates, all fittings being made of cast iron.

The tar and liquor from the retort house run into an underground concrete system 20 ft. by 45 ft. by 10 ft. in depth, where the tar and liquor condensed in the retort house are separated. The weak liquor collected at this point was used for sealing the hydraulic mains and finally found its way to the main ammonia liquor storage. The tar collected in the separator was pumped to an overground steel tank located near the retort house.

Alongside the condenser house there is an underground concrete ammonia tank measuring 35 ft. by 120 ft. by 10 ft. in depth, wherein is received and stored all the tar and liquor collected from the condensing and purifying plants. The tar separated at this point was sent to the overground tar tank and the ammonia delivered to the ammonia works.

PURIFYING PLANT

Buildings—The purifier house is 110 ft. long by 61 ft. wide and 36 ft. high and accommodates four purifiers. The building is of steel frame, the space between the frames and around the outside of the columns being built of brick. The roof is covered with hook tile carrying slate. A stairway leads from the ground floor to the operating floor around the boxes. This operating floor is built of steel plate. The roof is provided with a monitor extending the whole length of the building carrying a monitor sash. The general design of the building is similar to that of the other plant buildings, having granite trim and general handsome appearance. The purifying boxes measure 40 ft. by 20 ft. by 10 ft. deep and contain three layers of oxide with valve con-

nections to provide a triplex flow of gas. (Fig. 6.) The covers of the boxes are supplied with rubber lutes and holding down clamps and are handled with an overhead traveling crane. The system of valves and fittings is arranged so as to work the boxes either in forward or backward rotation.

In dumping a box, the oxide is dropped through openings in the bottom of the box onto a concrete floor. In filling a box, the wheelbarrows of oxide are raised to the operating floor by a Craig Ridgway steam hydraulic elevator.

METER HOUSE

From the purifying plant, the gas passes underground in a 24-in. main to the meter house, which is 40 ft. by 45 ft. by 20 ft., constructed of brick with steel roof trusses, the roof being of hook tile carrying slate. Space is provided in this building for four meters. When the coal gas plant was built, one 14-ft. meter was installed by the Nathaniel Tufts Meter Co., and supplied with a

FIG. 6. COAL GAS PURIFIER BOXES

Hinman drum. A photometer room was also constructed in the space provided for one of the future meters.

POWER PLANT

The power plant is housed in two buildings; one containing the boilers and the other containing the engines, generators and auxiliary machinery. The boiler house is 88 ft. by 65 ft. by 30 ft. high, of the same general construction as the other buildings on the plant. When first built three B. & W. 440-hp. boilers were installed, equipped for hand firing. A radial brick chimney was provided and additional forced draft was secured by means of an engine driven Sturtevant fan. An open-feed water heater was provided for the boiler water, but for the first few years very little exhaust steam was secured and the temperature of the water entering the boilers was never very high.

Engine House—The engine house is 46 ft. by 90 ft. and contains a main operating floor and basement. On the main operating floor are two 300-kw. cross compound, direct connected Allis Chalmers engines and generators. (Fig. 7.) These engines run condensing, utilizing salt water from the bay to operate barometric condensers. A 250-volt d.c. electric current is generated and is distributed through a switchboard to various circuits in the plant. Electric power is utilized for all possible operation of machinery.

In the cellar of the engine house are located the centrifugal boiler pumps, the condensing pumps and the fire pump, which utilizes salt water from the bay.

Water Tower and Wells—There are three sources of water supply for the works. Water from the city mains is used for boilers and other purposes where pure, fresh water is required. A set of driven wells was put down to a depth of about 50 ft., tapping underground veins of water, which some time after their construction unfortunately became contaminated with salt water from the bay. These wells are provided with two Davidson electric pumps, delivering the water into a tank on a tower, the tank having a capacity of 100,000 gal. of water and being elevated about 80 ft. from the ground.

RESULTS IN OPERATION

The coke made in this plant was of a very superior quality and found a ready sale for all domestic purposes. The yield of gas, tar and ammonia was satisfactory. When the plant was first started, it was very economical

FIG. 7. ENGINE ROOM

as to labor, but conditions later developed which caused the labor account to be high.

This was the pioneer plant in America of Dessau vertical retorts, which accounts for many of the operating difficulties encountered. There are now several very successful installations of vertical retorts on the Dessau system wherein American conditions have been more thoroughly taken into account.

WATER GAS PLANT

During the year 1915, it became evident that the capacity of the South Station for generating water gas would soon be exceeded by the demand, and it was decided to build a complete new water gas plant at the Sassafras Point Station. In July, 1915, the Bartlett Hayward Co. of Baltimore presented plans and specifications for this plant, which were accepted, and construction was commenced, gas being made in the new plant about the first of December, 1916. Mr. R. E. Slade had succeeded Mr. Carroll Miller as engineer for the gas company, and it was under his direction and supervision that the water gas plant was planned and constructed. The manufacture of water gas at the Sassafras Point Station involved the erection of a number of buildings, including a generator house, engine house, washer house, purifier house and a set of coal and coke bins. It also involved the erection of a relief holder, two oil tanks, extension of the boiler capacity, extension

of telfer lines, the moving of two station meters from the South Station to the new plant and also a 500,000-gal. tar tank. (Fig. 8.)

With the exception of the water gas machines, which were furnished and installed by the United Gas Improvement Co., all of the construction was undertaken by the Bartlett Hayward Co., although apparatus from several other firms was specified for certain purposes.

COAL AND COKE HANDLING

Adjoining the generator house and located between the generator house and the boiler house, a set of coal, coke and breeze bins was erected. These bins were about 120 ft. long and 23 ft. wide and were constructed of steel plates stiffened with steel beams supported on "H" columns roofed over with asbestos-protected metal. A steel partition runs lengthwise through the bunkers, so that boiler fuel may be separated from water gas fuel. In addition to this, wooden partitions were later put in, so that water gas coal and water gas coke could be separated and also different varieties of boiler fuel could be kept separate.

There are steel chutes with undercut gates serving the boiler house and the operating floor of the water gas plant.

Anthracite which is stored on the waterfront is delivered into the north end of the coal storage shed by the coal bridge. The telfer lines were extended to serve this coal store and coal is brought by telfers to a new hopper, which also takes coke, breeze and boiler coal handled by telfers from their respective storage piles. This hopper delivers to a motor driven 30-in. belt, having 205-ft. centers, with a capacity of forty tons per hr., which conveys the fuel up an incline to the proper elevation, then horizontally above the bins to the end of the bin house. A traveling unloader runs on rails above the bins and discharges the fuel where desired.

BUILDINGS

The generator house is of steel frame construction, the roof being carried on steel purlins and trusses, the trusses spanning the entire width and being supported on steel columns securely anchored to the building foundations, so that all loads are carried independent of brick side walls. A steel frame monitor, carrying swinging windows, is constructed on the roof. The end walls are carried up above the ends of the roof and are capped with stone. This building is 217 ft. long, 71 ft. wide and 31 ft. 10 in. high from the ground floor to the bottom chord of roof trusses. This building was so laid out as to accommodate five sets of water gas generating apparatus, but to date three sets only have been installed.

The exhaustor and pump house is 60 ft. long by 41 ft. wide and is of the same general construction as the generator house. The operating floor for the engines and exhausters is slightly above grade, and a pump room is provided somewhat below grade. Space was provided for three exhausters, only two being installed at present.

The tar extractor and washer house is 41 ft. long, 37 ft. wide and 21 ft. high. It has 13-in. brick walls with stone trim, the roof being carried on steel trusses anchored to 17-in. pilasters. There is a monitor on the roof with pivoted sash.

The purifier house is of steel frame construction with brick filled sides and gable roof, the roof being carried

FIG. 8. GENERAL VIEW SHOWING ORIGINAL COAL GAS PLANT AND WATER GAS PLANT ADDED IN 1915

by steel purlins and supported by trusses carried on steel columns. An outside steel stairway runs to the purifier floor. There is an additional stairway inside the building. The dimensions are 112 ft. by 61 ft. inside and 44 ft. 6 in. high from the ground floor to underside of roof trusses.

The roofs of all building are of terra cotta hook tile laid in cement with slate covering. All buildings are substantially built and have a handsome appearance.

EDITOR'S NOTES: This article is to be continued. Part II will describe in detail the new water-gas plant and Part III the Koppers combination-gas ovens.

Industrial Alcohol Act

At the present time industrial alcohol manufacturers are subjected to practically all the restrictions that are imposed upon the distiller of whiskey, with the result that production costs are unreasonably high.

To meet this situation, the Internal Revenue Bureau has drafted a bill, H. R. 5029, which is designed to make it possible for the Secretary of the Treasury and the Commissioner of Internal Revenue to relieve distillers of industrial alcohol from unnecessary and costly supervision in order that industrial alcohol may be made at minimum cost.¹

This bill provides for the registration, bonding and licensing of plants and warehouses for the manufacture, storage and distribution of alcohol which is to be used exclusively for non-beverage purposes. Those plants which are producing industrial alcohol exclusively at the present will be required to apply for registration within thirty days after the passage of the act. Legally established distilleries or bonded warehouses may also apply for permits to operate as industrial alcohol plants and warehouses. The alcohol may be produced from any raw materials and by any suitable process.

Such alcohol is subject to taxation but, by filing application and bond and obtaining a permit, a denaturing plant may be established at any industrial alcohol plant, and the denatured product sold free of tax for domestic or foreign use. Undenatured alcohol may be withdrawn, tax free, for the use of any university, research laboratory, or any hospital not conducted for profit.

The industry is to be regulated by the Commissioner of Internal Revenue (with the approval of the Secretary of the Treasury) in such manner that an ample supply, produced under the most efficient conditions, shall be available for scientific research and the development of fuels, dyes and other products.

¹Testimony of Deputy Commissioner Gaylord of Internal Revenue Board at hearing before the House Judiciary Committee.

Jubilee Meeting of the Iron and Steel Institute

THE Iron and Steel Institute (British) held its fiftieth annual meeting in London on May 8, 1919. The secretary reported the total membership of 2098. During the preceding year four new applications were received for grants of £100 each from Andrew Carnegie Research Fund, as follows: S. L. Hoyt, Minneapolis, for an investigation on the foreign inclusions in steel; J. N. Kilby, Sheffield, for an investigation on the basic open-hearth process, including its chemistry; G. Patchin, London, for research upon semi-steel and its heat treatment; J. A. Van den Broeck, Ann Arbor, for a continuation of studies on the effect of cold-working on the elastic properties of steel.

The Bessemer medal was presented to M. Leon Greiner.

The technical program contained a large number of excellent papers of which we present the following synopsis.

NATURE OF TRANSFORMATIONS IN IRON

A review of the evidence regarding the nature of the various transformations in iron was presented by Prof. K. Honda of the Imperial University, Sendai, Japan, "On the Non-Allotropic Nature of the A_1 Transformation in Iron." Regarding the change in physical properties with change in temperature as being due to variations in amplitude of atomic vibrations, an allotropic change occurs when these thermal vibrations exceed the limits of equilibrium of the then existent structure, and a new atomic configuration results. Since all changes take time, real allotropic transformations may spread over a considerable temperature range, and are difficult to distinguish from non-allotropic variations of physical properties as to temperature. However, the criterion of the latter is that the property of a substance bears a fixed relation to the temperature, unchanging with time, whereas allotropy is a transformation which proceeds at a definite temperature, if a sufficient time be allowed.

For pure iron there have been shown to be two real transformations, A_1 , occurring at 893-898 deg. C. (3 hours' time being required) and A_2 , occurring at 1385-1390 deg. (but a few minutes being required). A_2 —the magnetic transformation—on the other hand, begins at ordinary temperatures, its rate of change increases with temperature until at 785 deg. C. the test piece changes from the ferromagnetic to the paramagnetic state. An explanation of such changes is given, based upon the molecular theory of magnetism; wherein the author concludes that the A_1 transformation is not truly allotropic, but is the process of requiring the rotational energy of molecules, whose amount is a definite function of temperature.

In the case of carbon steels, there are two other transformations. A_3 , at 700-750 deg. C. is the eutectic transformation of cementite and ferrite, proved to take place at definite temperatures if the rate of heating or cooling is sufficiently slow, and therefore an allotropic change of phase. A_4 , at 215 deg. C. is the critical point of cementite and is of exactly the same variety as A_2 —that is, non-allotropic.

A. Cesáro, of Liège University, presented a "Note on the Liquidus in the Iron-Carbon Diagram." On the assumption that the liquidus should be a straight line, the

author shows mathematically that absolute rectilinearity cannot be obtained when using numerical values obtained by Carpenter and Keeling on any supposition as to the number of atoms of iron in a liquid molecule. He also shows that the nearest approach to plus or minus 8 deg., or within the experimental error, is when the iron molecule is regarded as Fe_2 and the melt assumed to consist of $Fe_2C \cdot Fe_2$ rather than of $F \cdot C$. Raoult's law, which leads to a straight line, presupposes dilute solutions of alloys not forming solid solutions upon solidification, neither condition being satisfied in the iron-carbon diagram. The author then applied the more general law to the Le Chatelier-Schroeder.

$$\ln z = \frac{Q}{2} \left(\frac{1}{T_0} - \frac{1}{T} \right)$$

where temperatures are expressed above absolute zero, and z is atomic per cent of solvent (gamma iron). Computing theoretical values of melting points T and comparing them with values observed by Carpenter and Keeling shows a much wider divergence than those found by Raoult's law, but as before a better agreement on the assumption that the melt consists of molecules of Fe_2C and Fe_2 .

MACRO-ETCHING AND MACRO-PRINTING

It is often very desirable to develop and print the macro structure of large steel sections for purposes of study and comparison. J. C. W. Humfrey, of the Inspection Service, describes a novel method of doing this in his paper "Macro-etching and Macro-printing." Sulphur printing on silk or silver bromide paper reveals the major segregates excellently, but the minor segregation—that occurring within the boundaries of the original crystal—is not revealed unless sulphur is very high. Besides, very great care is necessary to avoid movement during printing and insure uniform contact. Strong (10-20 per cent) solutions of hot HCl or H_2SO_4 act upon sulphide inclusions in much the same way, and require high sulphur metal for good results. Heyn's reagent (12 per cent Cu (NH_3), SO_4) is hardly sufficient to reveal minor segregations of phosphorus. Solutions of nitric acid are particularly useful for revealing fine flaws, which show after deep etching by a slight oozing when the surface is wiped clean and carefully dried with alcohol. It is very delicate in revealing locally decarburized areas, especially while the acid is still attacking. Acid cupric reagents are remarkably sensitive, but the surface should first be given a fine polish. At best any of these later methods must be photographed for record, which, in the case of large sections, will involve a reduction in scale.

Humfrey finds that a reagent such as

Cu (NH_3) $_4$ SO_4	120 g.
Conc. HCl	50 cc. (more or less)
H_2O	1000 cc.

is as delicate as any previously recommended, and can be used for very deep etching of a machined surface, after which it can be printed like a type-form on a proof press or in a letter-copying press. Etching is best done on the surface supported horizontally, starting with Heyn's solution, etching deeply to eliminate tool marks and surface hardening and then continuing with the new acid solution by pouring on fresh additions at intervals. Deposited copper can readily be wiped off; in case examination reveals insufficient attack, it should be resumed first with the neutral reagent. The strong relief is brought out by light buffing. To print, merely ink

with a proof roller, place on the bed of a copy press, cover with "glossy art paper," overlay with two thicknesses of broadcloth, and apply pressure.

This solution acts by attacking the purer portions which solidified first with greater vigor, leaving in relief the major and minor segregates, which thus print black on the proof. Some very beautiful examples of work on shell forgings are illustrated in the original paper.

GRAPHITIZATION IN IRON-CARBON ALLOYS

Whether graphite or cementite is the stable constituent of pure iron-carbon alloys was again discussed by K. Tawara and G. Asahara of Tokyo University. They cast a number of triangular ingots, in preheated clay molds, and studied the effect of six variables with regard to graphitization. First, chemical composition (that is to say, carbon content, the amount of silicon being held at 0.05 per cent or less, while the other impurities were very low) appeared not to be a decisive factor in graphitization. Graphite was always seen in a slowly cooled ingot containing from $2\frac{1}{2}$ to $3\frac{1}{2}$ per cent carbon, although in relatively larger amounts in higher carbon irons, which would be expected if the constituents appearing at primary solidification were austenite and graphite only. Second, the maximum temperature attained by the molten iron appeared to have no effect. Thus no excess decomposition of Fe_3C by superheating appeared to persist at the liquidus. Third, temperatures of casting up to 1400 deg. C. for a 3.3 per cent C appeared to cause no differences. Fourth, temperature of the mold had a large effect due to the speed at which it cooled the metal through the solidification range. Thus no graphite was found after pouring in a mold heated to 900 deg. C., held for 7 hr. at that temperature and then quenched. When cast in a mold heated to 1000 deg. C., held for 8 hr. and then quenched, graphite appeared in spots only. When cast in a mold heated to 1100 deg. C., held for $1\frac{1}{2}$ hr. and then quenched there was plenty of graphite. However, the same procedure in a mold at 1125-1128 deg. C. gave no graphite. The authors interpret the last results as meaning that the metal (3.3 per cent C) was held liquid in the mold, and when quenched it was white iron; a mold at 1100 deg. C. giving an optimum cooling rate through the mushy stage for graphitization. Fifth, when the mold is 1100 deg. C. and the subsequent cooling is slow, the metal is completely graphitized independently of the time it is held at 1100 deg. C. Sixth, with a mold at 1100 deg. C., the speed of subsequent cooling merely affects the method of deposition of the primary austenite, water quenching producing martensitic ground mass, and slow cooling producing pearlite and needle cementite.

From these experiments the authors conclude that homogeneous graphitization takes place during the slow cooling of the metal down to 1100 deg. C., covering a time longer than 30 min., and when uninfluenced by such accelerators as silicon and manganese, does not occur at 1000 deg. C. even after 8 hours' uniform heating. Consequently they believe that cementite in the melt is at least partially dissociated, and if time be given during solidification, the free carbon thus in existence will crystallize as graphite particles causing more cementite to decompose, enriching the melt in ferrite, the contemporaneous product of dissociation, when finally the remaining melt will have the composition of saturated austenite. Thus is the stable alloy produced. On more rapid cooling, decomposition of molten cementite is incomplete, whence the metastable "mottled" iron. The

authors consider a graphite crystal as being an element of the eutectic; the lamellar structure ordinarily expected of a eutectic is thus absent due to the slow cooling of the melt. Such crystals are surrounded by resolved austenite (needle cementite plus pearlite), as they should be, and not by ferrite resulting from a hypothetical decomposition of Fe_3C .

INFLUENCE OF RATE OF COOLING ON HARDENING CARBON STEEL

"An Experimental Investigation of the Influence of the Rate of Cooling on the Hardening of Carbon Steels" was described at considerable length by the prominent French metallurgist, A. M. Portevin of the Ecole Centrale des Arts et Manufactures, Paris, and his associate, M. Garvin. In a preliminary part the authors describe in detail their apparatus and method of tracing cooling curves at very rapid rates. A platinum couple whose elements were but 0.1 mm. in diameter was used in order that its heat capacity be negligible, and actual contact at the center of the cylindrical test piece was periodically verified by measuring the resistance, couple to specimen. In order that this contact might not be disturbed, the specimen and couple were both held stationary by a nickel-steel tube fixed to the upper head of a standard. Heating was done by a Meker blast lamp; when a predetermined temperature was reached the lamp was rapidly lowered, a quenching cup swung into place, and the specimen was cooled by a uniform flow of water. Automatic records were made photographically by a beam of light from a galvanometer mirror; the paper contains information as to necessary precautions and corrections to insure proper time and temperature registration.

Their problem was to determine for a given steel how the transformations, structure and hardness vary with different rates of quenching (τ from 700 to 200 deg. C. was the unit of comparison) and the initial temperature of quenching. Different speeds of quenching were had by using geometrically similar specimens of varying diameter; after quenching the pieces were broken across their center and the microscopy and Brinell hardness of the spot directly in contact with the thermocouple junction examined. A series of such curves for 1.07 C steel is illustrated in Fig. 1, and it is seen that rapid cooling suppresses transformations until 300 to 350 deg. C. Such cylinders are entirely martensitic and their hardness is uniformly close to 600. On cylinders 14 mm. in diameter and larger, however, this lower transformation Ar'' is suppressed and an upper one, Ar' , at

FIG. 1. AVERAGE COOLING CURVES AT THE CENTERS OF GEOMETRICALLY SIMILAR CYLINDERS OF STEEL, CONTAINING 1.07 PER CENT CARBON AND 0.08 PER CENT MANGANESE, QUENCHED IN WATER

635 to 665 (depending upon the speed) appears. Such cylinders show uniformly a troostitic core, of hardness, 400, surrounded by a shell of martensite of thickness decreasing as the diameter increases. There is therefore a critical range in the rate of cooling (in this particular steel, about 7 sec. from 700 to 200 deg. C.) at which the interval transformations suddenly change their nature and position on the temperature scale. When quenching at speeds near this rate, the same steel will sometimes appear troostitic, sometimes martensitic, and sometimes both Ar' and Ar'' are in evidence, giving a martensite-troostite complex.

Experiments by the authors demonstrate that composition has much to do with the critical rate. Particularly manganese will increase the critical time between 700 and 200, imparting quasi self-hardening properties. Variations in carbon also appear to have a marked influence. Eutectoid steels have slow critical rate as compared with either hypo-eutectoid or hyper-eutectoid, either of which tends to become troostitic with the separation of the pro-eutectoid constituents, ferrite or cementite respectively. This excess constituent may well be the cause of the phenomena, presenting nuclei unabsorbed into the austenite around which crystallization proceeds, correspondingly inducing formation of troostite. Unabsorbed nuclei may be the reason why previous heat treatment, mechanical working, method of manufacture, duration of heat and temperature of quenching all have an effect upon the speed of quenching.

In particular, raising the quenching temperature in the neighborhood of the critical rate tends to make Ar' disappear, as does also a second quenching. Also the authors point out that various facts already determined about quenching hold true at rates somewhat distant from the critical—thus τ varies as diameter of geometrically similar cylinders except at the critical rate, nor does hardness vary as the temperature of quenching (except at the critical rate), and with the same provision, the agitation, rate of circulation, or temperature of cooling water will not affect the hardness of drastic quenchings. By interrupting the quenching at various temperatures, the authors were also able to form troostite (γ iron-carbon solution $\rightarrow$ FeC + α iron complex) at temperatures as slow as 400 deg. Strong recalescence is exhibited in such curves, and microscopically the troostite is strongly marked and bulky, both the characteristics of a sharply defined reaction, much different from that which occurs when annealing martensite to troostite, osmondite or sorbite.

TWO PAPERS ON TOOL STEEL

"The Manufacture and Working of High-Speed Steel" was described in a paper by J. H. Andrew and G. W. Green of the Metallurgical Research Dept., Armstrong, Whitworth & Co., wherein they gave the practice at the Openshaw works in manufacture of steel bars with 14 per cent W, 3.8 per cent Cr, 0.5 per cent V, and 0.6 per cent C. Such material is melted in crucibles, and poured at 1420 ± 20 deg. C. into ladles, wherefrom it teemed at 1335 ± 5 deg. C. into chills, making a top-cast ingot 6 in. square and weighing 350 lb. After 30 min. the ingots are stripped, being then at 650 deg. and annealed in a gas-fired furnace for 48 hr. at 800 deg. C. Microsections now show excessive carbide segregation at the skin, and fine structure at the outer portion of the ingot. In the center is coarse-grained structure with thick walls of carbide.

Drillings from various parts of the ingots and cropings show practically no measurable segregation. This, as well as the entire absence of blowholes, is probably due to the small size of ingot, and the very quick solidification, due to the chill-mold and high alloy content.

Mechanical and heat treatment are resorted to in order to reduce this crystalline structure to an extremely fine grain, it having been found that 88 per cent reduction is necessary before the distorted carbide envelopes lose their dangerous form of loops and hooks. Whether reduction is done by rolling or forging is immaterial, as long as the working temperatures are correct, which, by the way, are greater than generally thought to be correct.

A good practice is cited as follows: After annealing, the ingots are preheated, attaining 820 deg. C. in 24 hr., then transferred to another furnace and brought to 1170 deg. in 4 or 5 hr. Cogging from 6 to $3\frac{1}{2}$ in. square was done under a $1\frac{1}{2}$ -ton hammer, occupying about $4\frac{1}{2}$ min., at which time the temperature was 1000 deg. C. Ten per cent of the head was cropped off; and any surface cracks gouged out with a steel tool, as is done after each reduction. Microsections now show well disseminated carbide in the outer portions, but at the center the envelopes are merely distorted.

After the $3\frac{1}{2}$ -in. billets are cut in half, they are aired under the fire-bars and finally charged into a cool-fired furnace, attaining a temperature of 1150 ± 20 deg. C. and soaking until the forge is ready for them. Forging one end to $1\frac{1}{2}$ in. requires slightly less than 2 min., during which time the temperature falls 50 deg. The large end is reheated and drawn under the same conditions. Microscopically, the carbide now is in laminated, band-like zones, occasionally appearing as semi-decomposed austenite.

From $1\frac{1}{2}$ in. the bars are tilted or rolled to $1\frac{1}{4}$ in., rolling starting at 1030 deg. C. and requiring 15 to 18 passes, consuming nearly 2 min., the temperature dropping about $10\frac{1}{2}$ deg. per pass. Tilting is done on each end separately as before, requiring about 2 min., during which the temperature drops from 1100 deg. to 850 ± 50 deg. At this point the carbide envelopes are broken up into grains, but these still assume laminated arrangement as to position.

In older practice the $1\frac{1}{4}$ -in. bars were then annealed by heating to 800 deg. C. in 24 hr., then damp the furnace from 3 to 6 hr., when the bars were furnace cooled during 36 hr. This required 3 days, and the structure was not refined (800 deg. being lower than the transformation range). Newer practice heats slowly to 900 deg. C., soaking a little time, cooling in furnace to 700 deg. C., and cooling in air. Cast structure is now eliminated, the bars have been softened from Brinell 616 to 250, and are ready for shaping into machine tools.

Lathe tools are hardened by gradually heating to a medium red heat, then quickly heating the nose to 1290-1300 deg. C., when it is quickly withdrawn and cooled in air-blast or oil attaining Brinell 650. Quick heating, consistent with adequate soaking, is desirable, since high and prolonged temperatures promote grain growth, without materially affecting any improper carbide distribution persisting to this point. A difference of 5 deg. in the maximum will increase the grain size 15 diameters (Figs. 2 and 3), while 10 deg. to 1310 will liquefy the carbide eutectics. At 1350 deg. the specimen is completely "crazed." (Fig. 4.) Tool failures may be due to persistent dendritic structure inherited

from too hot casting, rare segregations of slag or manganese sulphide, forging cracks, but most often carbide segregations forming banded laminations or grain envelopes.

A study of the microscopic and mechanical properties of several tool steels was presented by Dean J. O. Arnold, and Fred Ibbotson, of the University of Sheffield. Previous researches on plain carbon steels with the addition of a single alloying element has already distinguished the various carbides of chromium, vanadium, tungsten and molybdenum. In the complex mixtures used in these experiments, the same methods were used, namely, electrolysis of the tool steel in HCl (sq.gr. 1.02). The residue of carbides was then analyzed, whence formulæ could be ascribed.

It appears that the relative affinity of carbon for the alloying elements is V, Mo, W, Cr, and lastly Fe. Consequently, with the modest amount of carbon present (0.65 per cent) Fe₃C may be entirely absent in high W-V steels, the hard Cr₃C, also giving way to Cr₇C. Micro-

ceptable substitute for tungsten at the ratio of about 1 molybdenum to 2.7 tungsten.

STUDY OF THE OPEN-HEARTH PROCESS

Mr. B. Yaneske, of Vickers, Ltd., Sheffield, described in detail a typical melt which he had found best suited, in "Deoxidation, and the Influences of Lime on Equilib-

Steel No.	Efficiency Pointing	Type	No. of Tests	Lb. of Steel Removed
1574	1	V-Mo	Six	111 90
1578	2	V-W	Six	109 50
1576	3	V-W-Mo	Six	96 10
1577	4	W-Mo	Six	72 00
1579	5	W	Six	66 60
1575	6	Mo	Five	47 00

rium in the Acid Open-Hearth Furnaces." The nub of his process was to use extreme heat, and to control the silicon (and therefore oxygen) content of the bath as it approached the desired chemical content, by the careful addition of lime. For instance, he melts very hot to attain a very acid slag, since the acidity in equilibrium in-

FIG. 2. IDEAL HARDENED CONDITION. TEMPERATURE 1300 DEG. C. X 200, REDUCED ONE-THIRD

FIG. 3. OVERHEATED IN HARDENING. TEMPERATURE 1305 DEG. C. X 200, REDUCED ONE-THIRD

scopically, all the steels in annealed condition are similar, showing a pale background of an intermetallic solution overlaid by dark troostitic and paler sorbitic varieties of a pearlite of unknown composition, the whole being overlaid by nodules (sometimes streaks) of a brilliant white metal; doubtless a mixture of segregated carbides. When quenched from 1300 deg. C., the Mo-V steel shows well-marked allotriomorphic crystals of a mixed hardenite, which, here and there, are partially surrounded by a unique dark-etching pearlitic constituent, possibly a troostitic vanadium pearlite which does not transform into its hardenite until 1400 deg. A molybdenum steel with no vanadium does not show these areas. Other steels showed allotriomorphic crystals of hardenite of varying sizes, surrounded with thin-cell walls with fairly thick and very broken cell walls of cementite more or less segregated into nodules (sometimes in the crystals themselves).

Chemically the steels were designed to have constant carbon 0.65 per cent, chromium 2.85, silicon 0.4, manganese 0.2, phosphorus 0.015, sulphur 0.06. Vanadium when present was 1.25 per cent, molybdenum either 2 or 6 per cent and tungsten either 12 or 16 per cent. Efficiency tests were made by speeding up a lathe tool until it broke, and measuring the amount of steel removed, with the results shown in the accompanying table.

From the results molybdenum appears to be an ac-

creases with temperature. When clear melted and very hot the slag will contain about 48 per cent SiO₂, 33 per cent FeO and 16 per cent MnO, the latter variable as to the nature of the pig melted. At this point one may be added to maintain basicity, complete the elimination of silicon and to speed the "boil." As the heat progresses the slag gets lighter in color and more viscous, until finally SiO₂ becomes supersaturated and it is reduced by the metallic iron, this state of affairs evidencing itself by blowholes on the under surface of metal samples. Then limestone is added sparingly, with the ore, the former to satisfy the SiO₂ and the latter to continue to lower the carbon content of the bath. This method, by the way, is far better than to liquefy the slag by lowering the flame or by chilling with scrap, either of which increases the FeO in the slag by oxidizing metal. At a continuously high temperature, therefore, the decarbonization proceeds, a proper slag being about SiO₂, 58 per cent; FeO, 21 per cent; CaO, 5 per cent; MnO, 12 per cent, and appearing light green in a quenched sample, the metal being watched for bubbles, meanwhile, and fresh additions of lime made as they appear.

As the carbon content approaches that desired in the finished metal, lime additions are made with caution, and only as indicated by the appearance of blowholes from the reaction

0.4 per cent is evidence that Fe_2O_3 is extremely active as an oxidizing agent, even producing much free oxygen during heavy oreing. It is also continuously formed on the slag surface by furnace gases, as shown by the gradual thickening of the slag during the quiet finishing stage, when carbon in the bath is removed slowly with concurrent increase of Fe_2O_3 , from say 0.2 to 2.0 per cent in the slag.

Several decarburizing reactions may be written. Consider

This takes place at very slow rate, since when ore is added to the furnace Fe_2O_3 is destroyed and FeO rapidly increased. Again, 0.86 metal held 2 hr. under a slag containing 24 per cent FeO dropped to only 0.38 per cent C, with a corresponding decrease of FeO to but 20.8 per cent; calculation showing a large portion of the decarburization to be unaccounted for by the change $\text{FeO} \rightarrow \text{Fe}$

The reaction

is the only plausible reaction in which the percentage of iron in a slag can be raised. Since this actually occurs in the finishing stages, when C is below 0.15, it possibly is the predominant reaction. It doubtless also occurs during the boil, counteracting somewhat the effect of the then more prominent reaction

or possibly $\text{Fe}_2\text{O}_3 + \text{C} = \text{CO} + 2 \text{FeO}$

The authors conclude that the rapid reduction in carbon is due to gas reduction either direct or by Fe_2O_3 acting as a carrier; the latter being formed on the surface layers of the slag, and reacting with the slag-iron interface, most particularly of metal shot dancing in the slag whose quantity equals $\frac{1}{2}$ ton in a 100-ton bath. Therefore the use of a rich gas with as much air as the furnace can carry will afford best conditions for carbon removal—that is, rapid thickening of slag after more frequent ore additions. Consideration of the rate at which the bath is decarbonized after the boil (entirely by Fe_2O_3), and during the boil, also leads to the assumption that perhaps $\frac{1}{2}$ of the decarbonization by gas-reduction is due to contact between gas and metal shot during the boiling period.

MODERN STEEL METALLURGY

Mr. C. H. F. Bagley, technical supervisor for the South Durham Steel Co., presented a discussion of "Modern Steel Metallurgy," a calculation and comparison of processes, particularly as refers to the slags formed. In brief, it is a treatise on the metallurgical calculations of steel-furnace slags, so collated that given unit prices for different qualities of the necessary constituents, the best combination for any modern process may be actually determined with confidence, or, on the other

TABLE III

hand, the best process for a given set of conditions may be found when planning a new works. The author pays particular attention to the slag produced, laying emphasis upon the fact that steel making also involves slag making, and, other things being equal, it is true that any factor which lessens the quantity of slag made will at the same time increase the output of iron and lower its cost.

There is nothing particularly novel in the method of calculations. In general, given the analysis of metal charged and the amount of metal tapped, the amount of oxidation can easily be figured. Oxygen comes either from blast or ore; in the latter case, additional slag-forming impurities are added. These, with the impurities from the bath, will form a slag which in a given process varies within rather narrow limits at the end of the operation (whatever it may have been meanwhile) in order that it may be thin enough to pour, quiet, stable and non-corrosive. From such known composition, and a little auxiliary data as to mechanical losses, a metallic and non-metallic balance sheet can easily be obtained, giving the yield in metal per unit charged, the slag make and the weight of all additions.

Principal data are assembled in Tables I and II. As an instance of the results Table III summarizes the author's calculations on the various styles of duplex processes.

Lignite Utilization Board of Canada

Although Canada possesses large coal deposits, it has been necessary to import about 500,000 tons of anthracite from Pennsylvania at a cost of about \$5,000,000 per annum. The lignite deposits underlying various districts of the Provinces of Saskatchewan and Alberta are unsuited in the raw state to household use. By carbonizing, however, a coke is obtained which briquettes readily; two tons of the inferior fuel giving one ton of briquettes which approximate anthracite in heating value.

The Lignite Utilization Board was created to investigate machines and processes for carbonizing, briquetting, etc., and to construct a plant of commercial size for the production of domestic fuel. Consideration will also be given to the utilization of by-products and of powdered fuel for commercial power production.

Ramsay Memorial Fund

The committee for the Ramsay Memorial Fund for the United States reports the receipt of contributions totaling \$3700, which, after deduction of current expenses for printing, postage, etc., will leave about \$900 for transmission to the Fund headquarters in London. The committee had hoped to be able to transmit at least £1500 at this time, and will therefore welcome further contributions. Checks should be sent to the chairman, Dr. Charles Easkerville, 140th St. and Convent Ave., New York, or to the treasurer, Mr. William J. Matheson, 21 Burling Slip, New York.

Synopsis of Recent Chemical and Metallurgical Literature

Copper in Slags—A very important contribution to our knowledge as to the exact condition in which copper is held in furnace slags appeared in *Engineering and Mining Journal* for May 10, 1919, Volume 107, page 815, from the pens of C. G. MAIER and G. D. VAN ARSDALE. Their investigations were confined exclusively to Phelps-Dodge slag

when making a 30 to 40 per cent matte by smelting raw or roasted sulphides. Microscopically, such matte shows FeS islands in Cu_2S , ground mass, as in the globule of Fig. 6. Silver-nitrate is a good etching agent, deeply corroding the Cu_2S , which fact is utilized in determining whether any copper sulphide is present as a true solution in the slag. Under a microscope this reagent showed no effect on slag, while it actually dissolved more than 98 per cent of the copper from mattes and white metal. The equation is probably

Analyses of several blast-furnace and reverberatory slags showed an average residue of 0.7 per cent copper insoluble in AgNO_3 , with an average deviation of only 0.11, which figure (0.7 per cent) possibly represents the maximum solubility of some copper compound in such slags as 36 per cent SiO_2 , 10 per cent Al_2O_3 , 34 to 42 per cent FeO , 4 to 18 per cent $\text{CaO} + \text{MgO}$.

Table I shows various possible forms whereby copper may be held in slags.

Since no oxidized copper minerals were found in crystallized samples, and also since the copper dissolved in slags appeared to be a constant quantity, it is prob-

FIG. 6. BLAST-FURNACE SLAG. CHILLED UNETCHED INCLUSION IS UNALTERED MATTE. $\times 35$

able that no copper is held in solution as oxide. When remelting slag with various proportions of cuprififerous pyrite as plotted in Fig. 3, the per cent of copper in the resulting slag was quickly reduced to the amount originally held in solution. It is therefore probable that copper is not dissolved as metal, because the addition of pyrite already saturated with Cu_2S does not change the total in solution in the slag as would then be expected by the sulphidizing action of the pyrite. The addition of copper-free pyrite shown in the middle curve

(a) Matte is a variable complex material containing at least two constituents, one of which is readily attacked by Fe_2O_3 , and it is not proper to speak of its solubility as such. There must also, therefore, be a limiting size to the matte particles, below which they cannot exist in suspension.

FIG. 34. REVERBERATORY SLAG, ETCHED WITH HF. FUZZY CRYSTALLINE EDGES SHOW SEPARATION OF Fe_2O_3 . $\times 350$. FIG. 35. WELL-CRYSTALLIZED BLAST-FURNACE SLAG, ETCHED WITH HF COLUMNAR CRYSTALS WITH NO MAGNETITE. FIG. 36. FIRST-SKIN CONVERTER SLAG, HEAT-TINTED

reduces the dissolved copper, now assumed to be copper sulphide because of the distribution effect between slag and sulphide phase, and the idea that the copper is held as Cu_2S is further reinforced since the addition of CaS reduces the total copper because it increases the concentration of a common ion—in this case sulphur. The

FIG. 7. CHILLED BLAST-FURNACE SLAG; INCLUSION WITH LITTLE FeS . $\times 35$. FIG. 10. CHILLED BLAST-FURNACE SLAG; FeS CONSTITUENT ELIMINATED; WELL DEVELOPED GAS BUBBLES. $\times 150$

actual nature of this soluble sulphide is not known, but it very likely contains little FeS , because the latter ordinarily tends to disappear in the microscopic globules observed—in other words the shot of typical matte shown in Fig. 6 is usually replaced by spherical inclusions such as Fig. 7 or 10, where the FeS has largely disappeared, thus leaving particles of Cu_2S containing more or less FeS in solution. Iron sulphide constituent is not commonly observed even in slags from high grade matte.

Gas bubbles appear to be attached to the inclusions

FIG. 27. REVERBERATORY SLAG, ETCHED WITH NaOH . $\times 150$

shown in Figs. 7, 10 and 2, and the authors believe that this gas is derived from the disappearing FeS according to the reaction $\text{FeS} + 3\text{Fe}_2\text{O}_3 = \text{SO}_2 + 7\text{FeO}$. Of course, FeS might settle out physically as shown in Fig. 6, but this is never complete and occurs only at a narrow range of temperatures giving a mushy state. From microscopic evidence, the authors conclude that, since gas bubbles accompany the disappearance of FeS , the gas is probably SO_2 . It is logical to assume that Fe_2O_3 is the oxidizing agent since ferrous oxide and dissolved air would produce metallic iron and copper, respectively, neither of which was found. Ferric oxide is present, since it is required to form the magnetite ordinarily present in furnace slag. Magnetite occurs in converter slags in allotriomorphic crystals shown in Fig. 36. Magnetite is also present in reverberatory slags in holomorphic crystals often with fringes of dark colored Fe_2O_3 (Fig. 34), or in dendritic form (Fig. 27). However, magnetite was not found by these authors in their blast-furnace slags, whose structure is represented by Fig. 35.

Apparently, therefore, copper is held in furnace slags to a certain small extent as a true solution of sulphide, while the balance occurs as globules of white metal floated by attached gas bubbles. Continued settling would not appear to reduce the quantity of the latter, which could only be done by changing the composition of the slag so as to practically eliminate the occurrence of ferric oxide. Converter slags may contain as high as 0.5 per cent of copper in true solution, with the balance present as particles of white metal. As the blow continues the soluble copper continually decreases. Here is additional evidence that practically no copper silicates are formed in normal furnace practice.

Recent Chemical and Metallurgical Patents

Automatic Hardener.—T. J. FAY of Brooklyn, N. Y., has patented a special machine, illustrated herewith, designed for the automatic cambering and heat treatment of such parts as spring leaves. A heated plate of spring steel containing about 1 per cent carbon is heated to about 1535 deg. F., and placed on the lower anvil 7. The recessed upper head 11 then descends, shaping the bar to the desired radius. The entire assembly then descends past the oil sprays 40 and 41 into the tank below, which contain an oil layer 12 in. thick, resting upon a body of water. The passage of the oil layer requires 3 sec. when the hot metal is held in the water for 57 seconds. After this time the mechanism is elevated out of the fluid, and

AUTOMATIC HARDENER

the cool, cambered bar removed from the machine. The temperature of the metal and the relative time it is held in oil and water are subject to variation depending upon the kind of metal being treated. The entire equipment is electrically driven and by means of time relays the proper intervals can be absolutely fixed and repeated, so that at the end of the operation the core of the leaf will contain enough residual heat so that it may be properly annealed by blooming. (1,298,682; assigned to Standard Parts Co., Apr. 1, 1919.)

Ignition of D. & L. Cake.—C. W. ADAMS of Murray, Utah, notes that many times the usual oil-flame ignition for a Dwight & Lloyd sinter cake is not entirely satisfactory. In some cases such intense ignition fuses a crust on the top of the ore, making the charge semi-impervious to the passage of oxygen. This causes elemental sulphur to distill into the flues,

giving rise to the danger of explosive combustion. High loss in lead and silver is also characteristic of such practice. The inventor proposes to ignite the cake by spreading a thin layer of hot calcine on it. One-half inch of a bright red calcine having 12 to 15 per cent sulphur content has been satisfactorily used and has been found to obviate the disadvantages attending high-temperature ignition. For ease it is suggested that the hot calcine be discharged from a roasting furnace placed directly above the sintering machine. (1,299,892; assigned to American Smelting & Refining Co., Apr. 8, 1919.)

Resistors for Electric Furnace.—H. G. WEIDENTHAL of Cleveland, Ohio, suggests a novel arrangement for an electric furnace, whereby gangs of parallel, vertical resistors form the inner lining of the furnace laboratory. These terminate below in a conductor placed below a refractory hearth, which is banked up somewhat above their lower ends, and above are clamped to a conducting bar, in such a way that any damaged individual may be easily removed. Resistor gangs are so arranged as to allow spaces for pouring spout, and charging and inspection doors. For the individual resistors the inventor suggests molded rods of carborundum sand, coated with crystalline carborundum. At least one of each gang must have a small conducting rod in its axis, so as to start the current through the carborundum, which has a high resistance when cold. (1,304,425, assigned to J. H. Herron Co.; May 20, 1919.)

Converter Puncher.—CHARLES J. ARCH of Douglas, Ariz., has patented an automatic device for punching tuyeres in a copper converter. It consists of a frame carrying several air cylinders, one lined up for each tuyere, and with valves interlinked in a train so that each tuyere shall be punched by the piston rods in succession upon starting the first. Any plugged tuyere can also be skipped. Removable piston-rod ends are provided against wear, and a circular scraper is placed some distance ahead of the cylinder so that adhering slag may be peeled off the rod. The entire apparatus is counterweighted and normally connected by side arms to the connector shell and it tilts in a circle as the converter moves. Automatic releases are provided, however, so that the puncher is left stationary when the converter passes a limiting position. (1,303,755, May 13, 1919.)

Electrolytic Tungsten.—Present methods of drawing hot tungsten wire through diamond dies lubricated with graphite form an undesirable carbide alloy. F. G. KEYES of Cambridge, Mass., finds that WO_3 will dissolve in boric acid at 1200 to 1400 deg. C., and may then be electrodeposited upon, say, a fine tungsten wire. When the deposit has grown to sufficient size, it will be found somewhat ductile and can be drawn through dies of high-speed steel lubricated with talc (1,293,117; assigned to Cooper Hewitt Electric Co., Feb. 4, 1919.)

Crucibles.—F. J. TONE of Niagara Falls, has discovered that a very excellent crucible for melting metals can be made of 40 per cent graphite ground to 16 mesh, 40 per cent commercial magnesite, sintered in the electric furnace and ground to 40 mesh, and 20 per cent plastic refractory clay. This forms a plastic mass which can be made into crucibles and fired in the ordinary manner, and produces a superior, tough article which resists scaling or slabbing under heat variation in a superior manner. (1,303,993; May 20, 1919.)

Detinning Process.—WALTER ZACHARIAS of Pittsburgh, Pa., has discovered that when dry tin scrap is treated with chlorine, the reaction forming SnCl_2 , starts at local points when the concentration reaches a rather high figure, but rapidly spreads to all parts of the mass by the liberated heat. In order to prevent unduly high temperatures (which form undesirable iron chlorides) and loss in excess chlorine, he proposes to start the reaction when only low concentrations of chlorine are present by the addition of finely powdered metallic tin, which by virtue of its high specific surface will react at low temperatures and concentrations. He also proposes to place a hopper containing powdered tin above a suitable opening in the detinning vessel, so that this reagent can be introduced at will to regulate the temperature within, and to avoid the loss in time, chlorine, iron and tin chloride certain to follow undue irregularities. (1,283,016; Oct. 29, 1918.)

Improvements to Electric Furnaces.—W. E. MOORE of Pittsburgh, Pa., patents features designed to improve mechanical operation of electric furnaces. For instance, he recommends an arched bottom plate so that local heating may not destroy the furnace lining by buckling. A tilting arrangement consisting of stationary traction rollers, gear driven, is also suggested. Electrode holders should also be mounted at the side of the

FIG. 1. ELECTRODE HOLDER

furnace and capable of rotation about the axis of their supporting column, so that they may be swung away from the furnace roof when renewing roof or electrode. This arrangement also allows the hoisting chains to be drawn together to a point near the tilting center of the furnace, and thence leading them off to any convenient location for the motors. Electrode holders and arms themselves should preferably be split and hinged some-

what as shown in Fig. 1, to provide for the variation in sizes of carbons. Improved door and spout construction is also described. (1,304,350; May 20, 1919.)

Blast-Furnace Uptakes.—JULIAN KENNEDY of Pittsburgh, Pa., patents a blast-furnace top construction shown in Fig 2, involving inclined uptakes (6) discharging through restricted openings (10) into a downcomer branch (8), which latter connects with a similar set on

FIG. 2. BLAST-FURNACE TOP

the other side of the skip-bridge (4). This construction is proposed in order that a considerable proportion of the dust taken off by furnace gases or explosions may be arrested and fall back into the furnace proper before passing into the downtake. (1,303,914; May 20, 1919.)

Preparation of Iron Ore.—W. G. SWART of Duluth, Minn., and B. G. KLUGH of Anniston, Ala., note that certain fine or clay-bearing iron ores or concentrates, or high-sulphur ores, must be agglomerated before use in blast-furnaces. Commercially such agglomeration is best performed on an intimate mixture of fine ore and solid fuel, with sufficient water to make it plastic. Mixing of such wet, sticky masses is extremely difficult and expensive, and the inventors propose to take unwatered concentrates (or make up a thin pulp of the iron-bearing material), add dry pulverized coal or even wet peat, agitate thoroughly, and then filter the now well-mixed mass on a continuous filter so operated that the resulting cake shall have the proper proportion of moisture for sintering. (1,303,411, May 13, 1919.)

Lactic Acid.—By digesting sawdust with a solution of lactic acid, GEORGE A. RICHTER of Berlin, N. H., obtains a mixture containing reducing sugars. After filtering, the solution is treated with an excess of calcium carbonate and fermented by lactic acid bacteria. The excess CaCO_3 serves to neutralize the lactic acid as rapidly as it is formed during fermentation. Sufficient sulphuric acid is added to precipitate all the calcium as sulphate, which is filtered off, leaving a solution of lactic acid. (1,305,623; assigned to the Brown Company; June 3, 1919.)

Personal

The Salt Lake office of CHEMICAL & METALLURGICAL ENGINEERING has been closed and transferred to Rialto Building, San Francisco, Cal. Mr. Ernest E. Thum, formerly Western Editor, will be transferred to New York City as associate editor and Mr. L. W. Chapman, formerly with the Anaconda and duPont organizations, will go to San Francisco as Western editor.

DR. RAYMOND F. BACON, Director of the Mellon Institute of Industrial Research, received the honorary degree of Doctor of Science, on the occasion of the annual commencement of De Pauw University, Greencastle, Indiana, on June 10.

DR. H. K. BENSON has received his discharge as a captain in the research section of the nitrate division of the Army Ordnance and has returned to the University of Washington, Seattle, to resume his work as professor of chemical engineering and administrative head of the Department of Chemistry.

MR. FRANCIS S. BOSQUI will shortly open his office as metallurgical engineer at 90 West Street, New York City.

MAJOR ARTHUR S. DWIGHT, 11th Engineers, has recently returned to civil life after two years service in France with the A. E. F. On June 26 he addressed the New York Section of the A. I. M. E. on his war experiences.

MR. ELLWOOD HENDRICK, consulting editor of CHEMICAL & METALLURGICAL ENGINEERING, expects to sail for Venezuela, Wednesday, July 2.

COL. G. A. BURRELL has received the Distinguished Service Medal for his work as chief of the research Division, Chemical Warfare Service, during the war.

DR. VANNOY H. MANNING, director of the United States Bureau of Mines, on the occasion of the annual commencement of the University of Pittsburgh on June 13, received the honorary degree of Doctor of Engineering, in recognition of his noteworthy accomplishments in the investigation of problems of mineral technology. The university also conferred the honorary degree of Doctor of Chemistry upon DR. WILLIS R. WHITNEY, director of the Research Laboratory of the General Electric Co., Schenectady, New York, because of the valuable service which he rendered to the Government as a member of the Naval Consulting Board. These honorary degrees were given upon the recommendation of the Mellon Institute of Industrial Research, an integral part of the University of Pittsburgh.

PROFESSORS W. A. PATRICK and M. E. REID of the chemical department of the Johns Hopkins University will act as consulting chemists for the du Pont organization during part of the vacation period.

DR. J. W. RICHARDS, professor of metallurgy in Lehigh University and secretary of the American Electrochemical Society, leaves New York July 3 for Norway. After visiting some electrochemical plants in Norway and Sweden, and his son in Copenhagen, Dr. Richards will return about the middle of September.

MR. E. H. ROBE, recently assistant metallurgist for the Canadian Copper Co., Copper Cliff, Canada, has joined the editorial staff of *Engineering and Mining Journal*.

DR. JULIUS STIEGLITZ has been appointed chairman of the advisory committee on synthetic drugs to the Chemical Foundation, Inc., New York.

MESSRS. THORNE L. WHEELER and JOHN C. WOODRUFF have formed a partnership for the general practice of chemical engineering under the firm name of Wheeler & Woodruff, with offices at 280 Madison Ave., New York.

MR. EDWARD S. WIARD has resigned as consulting engineer for the Colorado Central Mines Co. and the Anondaga Mines Co. and will resume regular practice at 409 Boston Bldg., Denver, Colo.

MR. HORACE V. WINCHELL, president of the American Institute of Mining and Metallurgical Engineers, recently addressed the New York Section on the new developments at the Eastern end of the Mesabi Range in Minnesota.

Book Reviews

BOILER CHEMISTRY AND FEED WATER SUPPLIES.

By J. H. Paul 242 pages, illustrated. New York: Longmans, Green and Co.

The author has included a great amount of original data taken from his own experience. The book is written with the point of view of the usual technical training of the average power engineer in mind. Boiler chemistry is mainly concerned with the innumerable reactions that take place when natural waters are heated to around 400 deg. F. under a pressure of fifteen to twenty atmospheres. The chapter on water softening processes is too limited in scope. The book will serve a long neglected field and should be read by all engineers concerned with steam engineering.

WALLACE SAVAGE.

Current Market Reports

The Non-Ferrous Metal Market

Tuesday, June 24.—The prospects of the signing of the Peace Terms as well as the summer impetus toward increased construction work have greatly strengthened the metal market. Prices that had declined are now rising.

Aluminum:—No variation from the 33c. per lb. price on 98-99 per cent ingots is reported. Scrap sales are equally stable: Cast, 20-23c.; sheet, 20-23c., and clippings, 22½-26c. Sheets, 18 gage and heavier, 42c. Powder, \$0.70-1.40 lb.

Antimony:—There is a slight shortage in antimony supplies, wholesale spot bringing 8½c. and future 8-8½c. lb. Job lots, 8½c. lb.

Copper:—The copper market is showing considerable strength with 18c. lb. for spot and 18½c. for August futures. Predictions of 20c. copper are being made.

Copper sheets, hot-rolled.....	lb.	\$0 25½—	
Copper sheets, cold rolled.....	lb.	26½—	
Copper bottoms.....	lb.	25—	
Copper rods.....	lb.	19—	
Copper wire.....	lb.	18½—	\$0 19—
High brass wire and sheets.....	lb.	20½—	
High brass rods.....	lb.	19½—	
Low brass wire and sheets.....	lb.	30—	
Low brass rods.....	lb.	22½—	
Brazed brass tubing.....	lb.	31½—	
Brazed bronze tubing.....	lb.	36—	
Seamless copper tubing.....	lb.	30—	
Seamless bronze tubing.....	lb.	36—	
Seamless brass tubing.....	lb.	29—	
Bronze (gold) powder.....	lb.	1 00—	

Lead:—Lead has advanced 0.15c. and spot New York is 5.4s. and St. Louis 5.15c. Sheet lead, 8.5c. lb.

Tin:—Spot tin is quoted at 71c. lb. and August futures, 52c. Trading in tin will start in the New York Metal Exchange on July 7.

Zinc:—July spelter is bringing 7.15c. in New York and 7c. in E. St. Louis.

OTHER METALS

Bismuth.....	lb.	\$3.20 —	\$3.65
Cadmium.....	lb.	1.40 —	
Cobalt.....	lb.	2.50 —	3.50
Magnesium.....	lb.	1.75 —	2.10

Iridium.....	oz.	175.00 —	
Palladium.....	oz.	115.00 —	120.00
Platinum.....	oz.	105.00 —	
Silver.....	oz.	1.11½ —	

The Iron and Steel Market

The key to the steel market's future is the relation between the buying of steel for ordinary everyday consumption and the buying of steel for construction purposes or permanent investment. Such claims as have been made that the outlook is unfavorable have been based on a view that buying of steel for permanent or prolonged use, in other words for investment, is abnormally small, but such an argument defeats its own end, for it was there true the buying that has been in progress has been purely for current consumption, and that buying has lately represented more than 60 per cent. of the productive capacity.

The accepted estimate, however, is that normally more than 50 per cent. of the steel passes into permanent use. One of two things is the case. Either the current needs of the country have tremendously increased, so as to represent more than 60 per cent. of the capacity, or there really has been at least a moderate amount of buying of steel for permanent use or investment. In either case the steel outlook is obviously favorable, for buying for current use would naturally increase as unsettlement due to the war's ending passes, and buying for investment purposes is certain to come, or to increase. Investments must be made, for large quantities of capital have accumulated, awaiting investment, and steel in the form in which it leaves the mills is cheap, since finished steel products are now about 80 per cent. above their ten-year pre-war average, whereas the Dun and Bradstreet index numbers, covering commodities in general, stand at double their ten-year pre-war averages. Thus commodities in general will buy more steel than formerly. Steel has been affected less by the expansion, commonly though unfortunately called "inflation," than have commodities in general. Hence, when investments must be made, investment in steel is particularly attractive.

EFFECTS OF PEACE TREATY

While a great many views that were entertained just before and after the signing of the armistice have had to be modified, there is among others one view then entertained that has molded men's conduct, whereby light upon the future is thrown. That view was that investment would not proceed freely until the peace treaty should be signed. There can be no doubt that investments, particularly in works of construction, have been held back awaiting the formal establishment of peace by the signing of the treaty. The view that there would be an immediate or at least a prompt "deflation" in prices has been discarded, but the holding of the view for so long operated to delay the conversion of liquid capital into works of construction for investment purposes, involving the purchase of commodities and employment of labor.

It is true that some investors might be expected to anticipate the arrival of the formal peace, but the fact that as the months after the armistice passed, peace, with stable governments in Europe, seemed to recede instead of approach, had a tendency to discourage investors. Furthermore, many investments or undertakings rest upon the vote of boards of directors, many of the members being indisposed to anticipate, but to follow one plain policy, of refusing to endorse new ventures until peace should be sealed by the signing of the formal treaty by responsible and stable governments. That event having occurred, a great many new ventures will undoubtedly be launched quickly.

NEW CONSTRUCTION

By no means, however, has the inception of new construction awaited this time. By far the most accurate index to new construction such as particularly interests the steel trade is the monthly compilation of the Bridge Builders' and Structural Society of the amount of fabricated steel work let to the fabricating shops. In terms of monthly fabricating capacity the bookings have been as follows: January, 12 per cent; February, 12½ per cent; March, 17½ per cent; April, 24½ per cent; May, 49 per cent. When the volume of this business doubled from April to May it seems altogether reasonable to conclude that the signing of the peace treaty will result in a very large further increase.

There has been a curious reversal in the outlook as to the time when various new enterprises would be undertaken. Assuming, as practically everyone did, that a large quantity of construction work had piled up, the reasonable view not long ago, when it was expected that construction costs would gradually decline, was that the work undertaken first would be the more pressing work, that in which first cost was the less important consideration and time the more important, so that as time passed one class of work after another would be undertaken. Now, however, when the common view is that construction costs are approximately as low as they are likely to be for several years,

with possibilities that they will increase, the majority of investors are likely to be disposed to take hold at once. Their activities will be limited not so much by fear that the passage of time would write a depreciation on investments through construction costs declining as by inability to secure steel deliveries or labor with which to put the steel into employment. A rapid rather than a slow recovery in steel is therefore to be expected.

PRODUCTION

The low point in steel production fell at some time in May, probably about in the middle of the month, the rate, measured in steel ingot output, being down nearly if not quite to 50 per cent of capacity, the average production for the month having been 54 per cent. The computation is based upon the fact that 30 companies, which in 1918 made 84.03 per cent of the country's total steel ingots, reported 1,929,024 tons as their output in May, while the capacity of the country may be taken at 49,000,000 tons a year. The average 54 per cent rate for May compares with 65 per cent for April, 77 per cent for March, 85 per cent for February and 87 per cent for January. Since this low point of about 50 per cent. there has been a steady increase, consequent upon the increase in the buying of steel that began about the second week in May, and June production may be taken as having been at about 69 per cent of capacity on an average. Apart from such inroads upon output as may be made by midsummer weather, the recent 50 per cent rate will probably stand as the low record for several years.

PRICES

The test of the stability of the "regular" or "recognized" steel prices, those that became effective March 21, is the cutting that has occurred during the past three months. When with light mill operation there is no price cutting the evidence is clear that mills are afraid to cut, lest the bottom drop out of the market. Such a fear actuated the producers from the time of the armistice until April. Lately there has been price cutting in nearly all finished steel products, not by the majority of mills, but by a minority. The majority have been content to let the price cutters take such business as could be secured by that means, finding that their relations with their customers, and the service they furnish year after year, have been sufficient to bring them a very fair volume of orders, at the full prices. It seems now altogether improbable that there will be any further and general decline in steel prices. At the present time advances are not looked for, except perhaps in spots, but it is quite possible that the market will broaden so rapidly that some price advances will occur before the end of the year.

The Chemical Market

New York, June 26, 1919.

One of the most hopeful signs pointing toward a return to normality in the chemical trade is the increased domestic demand. This is attributed to the belief that the heavy stocks held by consumers when the armistice was signed have been used up.

HEAVY CHEMICALS:—The most interesting development in the heavy chemical field is the strong position taken by caustic soda and soda ash. With the decision last week of the Alkali Export Association to advance caustic soda to \$3.30 per cwt f.a.s. a strengthening tendency immediately invaded the market. Caustic soda has been in steady demand for some time, particularly from Japan and South America, but recently, realizing that offerings in second-hands were rapidly disappearing, buyers came heavily into the market with the domestic call showing the greater strength. Soda ash is running a close second in point of demand from both export and domestic quarters, and following the example of caustic soda has registered an advance, now being quoted at \$1.85-\$1.90 per cwt.

The recent arrival of several thousand cases of potash from Japan, with rumors of the future heavy importation of Alsatian potash, continue the weak position of all potash products.

Muriatic and sulphuric acids are in good demand for

Cuba and South America. Last week domestic dye manufacturers were in the market for sulphuric in quantities. Citric acid is again weak due to heavy arrivals from abroad, in particular from Italy. Bleaching powder has advanced 2c, due to absorption of resale material.

COAL-TAR PRODUCTS:—The improved tone of the crudes, noted in the last writing, stands at the same level. Benzol remains firm and is meeting a heavy demand from the rubber trade. As in the case of solvent naphtha, xylol, commercial, has been advanced because of heavy demand and short stocks. The same is true of phenol, with drums at 10-15c. per lb.

Intermediates are keeping their stride and as the month closes a better general business is reported from all quarters. Not only is the domestic phase on the increase, but South America is purchasing in the local market. A leading manufacturer is receiving orders for August delivery of paratoluidine and para-nitro toluol, but doubts whether he can meet the heavy July demands. Alpha-naphthylamine is hitting a good place for domestic use while H-acid is in good demand for export, not in large quantities but from a number of sources.

NAVAL STORES:—Although for a time there were no spot stocks of turpentine on the market here, owing to the heavy call from Europe—particularly Scandinavia—new supplies have meantime arrived sufficient to take care of the normal domestic demand. During the past two months London has purchased approximately 60,000 bbl., which is thought to have filled her needs. Domestic buying has fallen off due to high prices. The result is an easier market.

The principal reason for the firm tone of rosins is the heavy export demand. With only one-half the normal crop of rosins being made this year a scarcity is predicted if present buying continues. However, with the exception of the pale grades, spot stocks here are normal. Savannah, where buying is also brisk, reports a shortage of pale grades. South America and the United Kingdom are the principal operators in rosins. Other naval stores show a slight rise in sympathy with rosins.

CRUDE RUBBER:—It is estimated that present plantation stocks in London amount to 24,000 tons, with 10,000 tons in the Far East, and over 60,000 tons in the United States. In view of this condition, the market is weak, dealers being the principal operators. For the past week there has been an active dealers' demand for distant positions, presumably to cover short sales at a profit. Manufacturers, however, manifest no interest.

Paras are weak, in sympathy with planations. Manufacturers have fair-sized stocks on hand, future selling higher than spot. A Singapore cable reads: "Large holders primary markets weakening. Market weak," while London wires: "Market stagnant awaiting political developments."

OILS:—The interrupted European demand remains the dominant factor, vegetable oils now going even into Germany and Austria. Domestic buyers realizing that the export demand will hold up the price are purchasing at prevailing levels. There is a scarcity not only of spot stocks, but of August and September futures. Linseed oil is particularly scarce, owing to short crop of seed, and heavy demand. Although several shipments of seed have arrived from Argentina recently, linseed oil is firm at \$1.88-\$1.89 per gal.

The recent embargo placed by Spain on the export of olive oil is felt here in the small arrivals and the stiffening price. The commercial grade is held at \$2.30 to \$2.50 per gal.

During the past two weeks, oils, both vegetable and fish, have risen sharply. Winter pressed menhaden, quoted at the last writing at 90-92c per gal., has added 20c. to its market value. The foreign demand has developed to such an extent that surplus stocks are used up, necessitating reliance on the new catch of fish. Another factor in sending up fish oils is the fact that when these oils were at the lower level they were substituted wherever possible for the higher priced vegetable oils.

SHELLAC:—The shellac situation has not been aided by the information that the steamer "City of Rangoon," with about 5000 packages of shellac on board, had been in colli-

sion in mid-ocean with a Brazilian steamer and had put back to Gibraltar. While small amounts continue to arrive all go to fill back orders. Most dealers have stopped quoting and are merely delivering on previous sales or allotting small quantities to their regular trade. One dealer, however, is quoting orange, superfine at \$1-\$1.15, spot, in one and two-bag lots; futures, Sept. to Dec. deliveries, TN, 72-75c, orange, superfine, 80-85c, and bone dry at 80-85c. It is not until September that any relief is expected.

WAXES:—Firm tone and higher prices characterize the wax market, carnauba and stearic acid showing the sharpest increase. The Brazilian crop of carnauba is exceedingly light, and trading has become speculative, with Europe buying heavily. Three shipments of this wax are expected soon, but they will have little effect, being already sold. With production cut because of the warm weather and a shortage of basic manufacturing supplies, stearic acid is scarce and higher in price. With a general shortage of spot stocks prices of waxes are expected to mount still higher.

St. Louis, Mo., June 23.

The past two weeks have shown a steadily increasing activity in most branches of the heavy chemical market, according to local producers. Demand for sulphuric acid from the fertilizer manufacturers and for sodium bisulphate or nitre cake, especially, has grown to such proportions that one of the best informed men on the subject characterized the market as having "gone crazy." Producers of nitre cake say that there is no accounting for the present demand for this item which until recently was "dumped" for indefinite storage at plants where it was a by-product. A nearby producer is understood to be digging into such a storage pile of nitre cake for the first time in years.

Sulphuric Acid—Sixty per cent sulphuric acid was the most active item on the list here in the last two weeks. This may be accounted for by the fact that producers who asked \$12.50 to \$14 a ton several weeks ago, on noting the reluctance to buy, accepted contracts at \$11.50. Heavy sales at this figure are reported. The 66 per cent grade, still quoted at \$18 a ton, is stationary, but firm. The same is true of oleum.

Muriatic Acid—A large number of sales is reported in this commodity at the quotation of the previous report, \$22 a ton for the 18 per cent grade. The starch, glucose and graniteware people are alike actively in the market for the chemical.

Sodium Sulphate (Salt cake)—The demand for this item fell off during the fortnight sufficiently to induce manufacturers to offer it at a dollar concession, or \$18 to \$20 a ton, according to grade and quantity.

Sodium Bisulphate (Nitre Cake)—A sudden and unaccountable demand developed in the last week or two, but heavy stocks maintained the price at \$4 to \$5 a ton.

Nitric Acid—This branch of the market in comparison to the others is quiet. The price, however, remains firm at 10 to 10½ cents per pound for the 38 Baumé.

Zinc Chloride—In view of the conditions in railroad circles this item (used largely for treating ties) is considered fairly active by producers here. Compared to previous week, however, the demand has fallen off somewhat. The price remains stationary at 4 cents for the 50 per cent solutions.

Zinc Oxide—Developments of unusual importance are expected in the Mid-West zinc-oxide market momentarily, as a result of the action of Eastern producers in doing away with quarterly price announcements. While no definite statement of policy is forthcoming today, indications are that this market will now become wholly competitive with price changes developing from day to day or at most from week to week, rather than from quarter to quarter, as in previous years. The present quarter expires on July 1 and the basis of doing business in this item is to be readjusted within the next few days. With this condition prevailing an almost total cessation of buying would be expected. Producers, however, report an excellent demand. Prices at which current business is being done range from 8 to 9 cents a pound according to the lead-sulphate content in car lots and half a cent additional for smaller quantities. It is rumored that the inauguration of an open market will result in an advance in prices of this item.

Coal Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude.....	lb.	\$1.00	\$1.10
Alpha naphthol, refined.....	lb.	40	1.50
Alpha naphthylamine.....	lb.	35	50
Aniline oil, drums extra.....	lb.	05	1.50
Aniline salts.....	lb.	28	33
Anthracene, 80% in drums (100 lb.).....	lb.	90	1.00
Benzaldehyde, (f.c.).....	lb.	1.00	1.10
Benadine, base.....	lb.	95	1.55
Benadine, sulphate.....	lb.	90	1.10
Benzoic acid, U. S. P.....	lb.	1.00	1.10
Benzoate of soda, U. S. P.....	lb.	24	1.10
Benzol, pure, water-white, in drums (100 lb.).....	gal.	231	27
Benzol, 90%, in drums (100 lb.).....	gal.	231	27
Benzyl chloride, 95-97%, refined.....	lb.	35	40
Benzyl chloride, technical.....	lb.	35	40
Beta naphthol benzoate.....	lb.	4.00	4.50
Beta naphthol, sublimed.....	lb.	75	80
Beta naphthol, tech.....	lb.	45	55
Beta naphthylamine, sublimed.....	lb.	25	2.35
Cresol, U. S. P., in drums (100 lb.).....	lb.	18	23
Ortho-cresol, in drums (100 lb.).....	lb.	23	25
Cresylic acid, 92-95%, straw color, in drums.....	gal.	85	90
Cresylic acid, 95-97% dark, in drums.....	gal.	80	85
Cresylic acid, 50%, first quality, drums.....	gal.	60	
Diethylbenzol.....	lb.	07	10
Diethylaniline.....	lb.	1.50	2.25
Dimethylaniline.....	lb.	55	60
Dinitrobenzol.....	lb.	25	37
Dinitrochlorobenzol.....	lb.	25	28
Dinitrophenalene.....	lb.	45	55
Dinitrophenol.....	lb.	1.50	1.75
Dinitrotoluenol.....	lb.	38	45
Dip oil, 25% tar acids, car lots, in drums.....	gal.	38	46
Diphenylamine.....	lb.	70	75
H-acid.....	lb.	1.55	2.25
Metaphenylenediamine.....	lb.	1.20	1.80
Monochlorobenzol.....	lb.	1.10	1.14
Monothylaniline.....	lb.	1.50	1.75
Naphthalene, crushed in bbls. (250 lb.).....	lb.	06	08
Naphthalene, flake.....	lb.	061	071
Naphthalene, balls.....	lb.	091	10
Naphthionic acid, crude.....	lb.	1.00	1.10
Nitrobenzol.....	lb.	13	15
Nitro-naphthalene.....	lb.	35	45
Ortho-toluenol.....	lb.	17	20
Ortho-amidophenol.....	lb.	6	10
Ortho-dichlorobenzol.....	lb.	15	20
Ortho-nitro-phenol.....	lb.	1.25	1.35
Ortho-toluidine.....	lb.	32	45
Ortho-nitro-toluenol.....	lb.	30	40
Para-amidophenol, base.....	lb.	2.60	3.50
Para-amidophenol, H. Cl.....	lb.	2.75	3.25
Para-dichlorobenzol.....	lb.	06	10
Paranitraniline.....	lb.	1.00	1.25
Para-nitro-toluenol.....	lb.	1.35	1.50
Paraphenylenediamine.....	lb.	3.00	3.25
Para-toluidine.....	lb.	30	35
Phenol, U. S. P., drums (deat), (240 lb.).....	lb.	1.15	2.13
Phenol, U. S. P., drums (deat), (240 lb.).....	lb.	1.10	1.13
Pyridine.....	gal.	2.50	3.25
Resorcin, technical.....	lb.	6.50	7.25
Resorcin, pure.....	lb.	6.50	7.25
Salicylic acid, tech., in bbls. (110 lb.).....	lb.	20	30
Salicylic acid, U. S. P.....	lb.	25	35
Salicyl.....	lb.	1.00	1.25
Solvent naphtha, water white, in drums, 100 gal.....	gal.	18	20
Solvent naphtha, crude, heavy, in drums, 100 gal.....	gal.	18	24
Sulphanilic acid, crude.....	lb.	25	30
Toluidine.....	lb.	1	2.50
Toluidine, mixed.....	lb.	7	45
Toluenol, in tank cars.....	gal.	22	24
Toluenol, in drums.....	gal.	22	30
Xylol, drums, 100 gal.....	gal.	22	30
Xylol, pure, in drums.....	gal.	37	45
Xylol, pure, in tank cars.....	gal.	35	45
Xylol, commercial, in drums.....	gal.	22	27
Xylol, commercial, in tank cars.....	gal.	22	27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow.....	lb.	\$0.42	\$0.44
Beeswax, refined, yellow.....	lb.	.46	.48
Beeswax, white pure.....	lb.	.65	.68
Carauaba, No. 1.....	lb.	.88	.92
Carauaba, No. 2, regular.....	lb.	.88	.92
Carauaba, No. 3, North Country.....	lb.	.55	.56
Japan.....	lb.	.183	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb.	.06	.073
Paraffine waxes, crude scale 124-126 m.p.....	lb.	.07	.08
Paraffine waxes, refined, 118-120 m.p.....	lb.	.083	.083
Paraffine waxes, refined, 128-130 m.p.....	lb.	.094	.10
Paraffine waxes, refined, 133-135 m.p.....	lb.	.11	.12
Paraffine waxes, refined, 135-137 m.p.....	lb.	.123	.12
Stearic acid, single pressed.....	lb.	.20	.213
Stearic acid, double pressed.....	lb.	.23	.233
Stearic acid, triple pressed.....	lb.	.24	.25

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal.	\$0.70	
Pine tar oil, rel., sp. gr. 1.025-1.035.....	gal.	.43	
Pine tar oil, rel., sp. gr. 1.025-1.035 tank f.o.b. Jacksonville, Fla.....	gal.	.33	
Pine tar oil, double rel., sp. gr. 0.965-0.990.....	gal.	.58	
Pine tar, rel., thin, sp. gr. 1.080-1.060.....	gal.	.34	
Turpentine, crude, sp. gr. 0.900-0.970.....	gal.	.61	
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....	gal.	.24	
Hardwood oil, f.o.b. Mich., sp. gr. 1.06-1.08.....	gal.	.24	
Pineewood creosote, rel.....	gal.	.48	

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.....	280 lb.	\$15.00	\$16.25
Rosin E-I.....	280 lb.	16.50	16.90
Rosin K-N.....	280 lb.	16.90	17.75
Rosin W, G-W, W.....	280 lb.	17.75	18.60
Wood rosin, bbl.....	280 lb.	15.00	
Spirits of turpentine.....	gal.	1.10	
Wood turpentine, steam dist.....	gal.	1.07	
Wood turpentine, dest. dist.....	gal.	.98	
Pine tar pitch, bbl. (500 lb.).....	200 lb.	8.00	8.25
Tar, kila burned, bbl. (500 lb.).....	200 lb.	12.50	13.50
Rectort tar, bbl.....	280 lb.	13.50	14.50
Rosin oil, first run.....	gal.	.81	.833
Rosin oil, second run.....	gal.	.83	1.023
Rosin oil, third run.....	gal.	.85	1.023
Rosin oil, fourth run.....	gal.	.88	1.05

Solvents

73-76 deg., steel bbls. (85 lb.).....	gal.	\$0.3334	
70-72 deg., steel bbls. (85 lb.).....	gal.	.31	
68-70 deg., steel bbls. (85 lb.).....	gal.	.28	
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal.	.233	

Crude Rubber

Para—Upriver fine.....	lb.	\$0.55	0.553
Upriver coarse.....	lb.	.53	.54
Upriver carbu ball.....	lb.	.333	.34
Plantation—First latex crepe.....	lb.	.393	.403
Ribbed smoked sheets.....	lb.	.363	.39
Brown crepe, thin, clean.....	lb.	.34	.36
Amber crepe No. 1.....	lb.	.36	.38

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls.....	lb.	\$0.19	\$0.21
Castor oil, AA, in bbls.....	lb.	.21	.23
China wood oil, in bbls.....	lb.	.21	.22
Cocoonut oil, Ceylon grade, in bbls.....	lb.	.193	.20
Cocoonut oil, Cocio grade, in bbls.....	lb.	.21	.22
Corn oil, crude, in bbls.....	lb.	.19	.22
Cottonseed oil, crude (40 mill).....	lb.	.16	.22
Cottonseed oil, summer yellow.....	lb.	.26	.27
Cottonseed oil, winter yellow.....	lb.	.26	.27
Linseed oil, raw, car lots.....	gal.	1.13	1.90
Linseed oil, raw, tank cars.....	gal.	1.84	1.90
Linseed oil, boiled, car lots.....	gal.	1.90	1.93
Olive oil, commercial.....	lb.	2.30	2.40
Palm, Lagos.....	lb.	.17	.18
Palm, bright red.....	lb.	.16	.163
Palm, Niger.....	lb.	.17	.18
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.23	.23
Peanut oil, refined, in bbls.....	lb.	.26	.27
Rapeseed oil, refined in bbls.....	gal.	1.55	1.60
Rapeseed oil, blown, in bbls.....	gal.	1.60	1.65
Soya bean oil (Manchurian), in bbls., N. Y.....	lb.	.19	.193
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.163	.17

FISH

Winter pressed Menhaden.....	gal.	\$1.10	
Yellow bleached Menhaden.....	gal.	1.12	1.15
White bleached Menhaden.....	gal.	1.14	1.20
Blown Menhaden.....	gal.	1.18	1.25

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated.....	ton	\$25.00	\$36.00
Barytes, off color.....	ton	22.00	27.00
Blanc fixe, dry.....	lb.	.033	.043
Blanc fixe, pulp.....	ton	30.00	45.00
Casim.....	lb.	.05	.07
Chalk, English, extra light.....	lb.	.05	.07
Chalk, English, light.....	lb.	.043	.06
Chalk, English, dense.....	lb.	.04	.06
China clay (Kaolin), imported, lump.....	ton	25.00	35.00
China clay (Kaolin), imported, powdered.....	ton	30.00	60.00
China clay (Kaolin), domestic, lump.....	ton	10.00	20.00
China clay (Kaolin), domestic, powdered.....	ton	40.00	40.00
Feldspar.....	ton	11.00	15.00

Fluorepar, acid grade, lump, f.o.b. mines.....	net ton	\$30.00	\$35.00
Fluorepar, acid grade, ground, f.o.b. mines.....	net ton	35.00	45.00
Fuller's earth, domestic, powdered.....	ton	30.00	40.00
Fuller's earth, imported, powdered.....	ton	30.00	40.00
Pumice stone, imported.....	lb.	.03	.06
Pumice stone, domestic.....	lb.	.023	
Shellac, TN.....	lb.	.60	
Shellac, D.....	lb.	.60	
Shellac, V. S. O.....	lb.	1.15	
Shellac, Diamond I.....	lb.		
Shellac, orange, fine.....	lb.	.88	
Shellac, orange, superfine.....	lb.	1.00	1.15
Shellac, A.C. garnet.....	lb.	.90	
Shellac, bleached, bone dry.....	lb.	1.15	
Shellac, bleached, first ground.....	lb.	2.00	3.00
Soapstone.....	ton	15.00	25.00
Talc, domestic.....	ton	16.00	60.00
Talc, imported.....	ton	55.00	60.00

Refractories

Following prices are f. o. b. works:

Chrome brick.....	net ton	90-100 at Chester, Penn.
Chrome cement.....	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay.....	net ton	35-45 at Clearfield, Penn.
Clay brick, 2nd quality.....	net ton	30-35 at Clearfield, Penn.
Magneate, dead burned.....	net ton	50-55 at Chester, Penn.
Magneate brick, 9 x 4 1/2 x 2 1/2.....	net ton	80-90 at Chester, Penn.
Silica brick.....	net ton	41-45 at Mt. Union, Penn.

Ferro-alloys

All prices f. o. b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$220.00	
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon.....	lb.	32	\$0.40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon.....	lb.	.70	
Ferro-manganese, 70-80% Mn.....	gross ton	100.00	125.00
Spiegelisen, 16-20% Mn.....	gross ton	35.00	50.00
Ferro-manganese, 90% Mn.....	gross ton	45.00	50.00
Ferro-silicon, 50%.....	gross ton	90.00	115.00
Ferro-silicon, 75%.....	gross ton	150.00	175.00
Ferro-silicon, 10-15%.....	gross ton	45.00	60.00
Ferro-tungsten, 70-80% per lb. of contained W.....	lb.	1.30	1.60
Ferro-uranium, 35-50% of U.....	lb.	7.00	
Ferro-vanadium, 30-40% per lb. of contained V.....	lb.	5.50	7.00

Resales and overstocks make above prices approximate.

Ores and Semi-finished Products

Chrome ore, 35-40% Cr ₂ O ₃	unit	\$0.70	
Chrome ore, 48% and over.....	unit	.80	
Coke, foundry, f.o.b. mines.....	net ton	5.00	\$5.50
Coke, furnace, f.o.b. mines.....	net ton	4.50	5.00
Petroleum coke, f.o.b. Atlantic seaboard.....	net ton	16.00	16.50
Fluorspar, gravel, f.o.b. mines.....	net ton	20.00	25.00
Manganese ore, 45% Mn and over.....	unit	.60	.65
Manganese ore, chemical (MnO ₂).....	gross ton	60.00	70.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂	lb.	.75	.85
Tungsten, Scheelite, 60% WO ₃ and over per unit of WO ₃	unit	9.00	11.50
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃	unit	6.50	8.00
Uranium oxide, 96%.....	lb.		
Vanadium pentoxide, 97%.....	lb.	6.00	
Pyrites, foreign, lump.....	unit	.15	
Pyrites, foreign, fine.....	unit	.15	
Pyrites, domestic, fine.....	unit	.14	
Ilmenite, 50% TiO ₂	net ton	30.00	40.00
Rutile, 95% TiO ₂	net ton	200.00	
Carbottite, minimum 2% U ₃ O ₈ , per lb. of U ₃ O ₈	lb.	2.75	3.00

Resales and overstocks make above prices approximate.

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags.....	bbl.	\$2.30	
Lump lime, common, including container.....	300 bbl.	2.65	
Common brick, at dock.....	M.	15.00	
Hollow building tile.....	M.	19.40	
At factory, Perth Amboy, N. J. 8x12x12.....	M.	21.60	
Yellow pine, 3x4 to 8x8, 20-24 ft. long.....	M.	7.00	40.00
Yellow pine, 3x4 to 8x8, 20-24 ft. long at Chicago.....	M.	39.50	
Yellow pine, 3x4 to 8x8, 20-24 ft. long at St. Louis.....	M.	37.00	
Roofing, tar felt (14 lb. per 100 sq.ft.).....	ton	21.00	
Roofing, tar pitch (in 400-lb. bbl.).....	ton	21.00	
Roofing, asphalt pitch.....	ton	34.00	
Roofing, asphalt felt.....	ton	65.00	
Roofing, slate-surfaced, per roll of 108 sq.ft.....	ton	60.00	
Roofing, slate-finished shingles, 100 sq.ft.....	ton	5.00	
Linseed oil, raw in barrels.....	gal.	1.93	
Linseed oil, 5 gal. cans.....	gal.	2.06	
Red lead, dry, 100 lb. keg.....	lb.	.13	
Red lead, in oil, 100 lb. keg.....	lb.	.143	
Red lead, dry, 5 lb. cans.....	lb.	.15	
Red lead, in oil, 5 lb. cans.....	lb.	.163	
White lead, dry and in oil, 100 lb. keg.....	lb.	.13	
White lead, dry and in oil, 25 and 50 lb. kegs.....	lb.	.133	
White lead, dry and in oil, 5 lb. cans.....	lb.	.15	

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....	100 lb.	\$2.45	
Angles, 3 to 6-in, 1-in. thick.....	100 lb.	2.45	
Tees, 3-in. and larger.....	100 lb.	2.45	
Plates.....	100 lb.	2.66	
Rivets, structural, 1-in. and larger.....	100 lb.	4.30	
Rivets, conehead for boilers, 1-in. and larger.....	100 lb.	4.35	
Sheets, No. 28 black.....	100 lb.	4.35	
Sheets, No. 10 black annealed.....	100 lb.	5.70	
Sheets, No. 28 galvanized.....	100 lb.	5.70	

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c. all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

DUNCAN—The Ash Peak Mines Co. plans to build a mill to have a yearly capacity of 45,000 tons. A. Murphy, superintendent.

GLOBE—The Gila Monster Co. plans to build a 10 stamp mill and is in the market for a crusher, two tables, six tanks and an 80 hp. engine. Estimated cost, \$50,000. W. H. Seaman, superintendent. Noted May 15.

GLOBE—The Jumbo Mining Co. plans to build a 25-ton cyanide mill to handle tailings. W. T. Massonette, Waco, Tex., superintendent.

MIAMI—The Greater Miami Mining & Milling Co. plans to build a 100-ton concentration mill.

MIAMI—The Miami Mining & Milling Co. plans to build a 50-ton concrete flotation mill at Dook Station, near the Arizona Eastern Railway.

TUSCON—The Yellow Bird Mining Co. plans to build a silver-lead furnace at its property 32 miles west of Tucson to treat 50 tons daily. S. W. Purcell, manager.

WINKLEMAN—The Aztilan Mining Co. will build a 100-ton mill and is in the market for equipment for same. Estimated cost, \$150,000. H. Whitcomb, manager.

California

AVALON—The city voted \$55,000 bonds for the construction of a gas plant. A. B. Waddingham, Tajo Building, Los Angeles, city engineer.

BISHOP—A. D. Schivley, town clerk, rejected bids opened June 2 for the construction of a sanitary sewerage system and sewage treatment tank. Estimated cost, \$35,000. New bids will soon be received. Olmsted & Gillette, 1112 Hollingsworth Building, Los Angeles, engineers.

WASHINGTON—W. F. McCutcheon, San Francisco, plans to rebuild its 40-stamp mill, compressor building, etc., near here, recently destroyed by fire. W. L. Williamson, superintendent.

Connecticut

PERRYPONT MANOR—The Northern New York Milk Co. recently incorporated with \$500,000 capital stock, will install laboratory equipment for both dry and condensed milk plant, in connection with the milk station, evaporating plant and milk shipping station which it plans to build. Estimated cost, \$200,000. Address: F. H. Redfield, Adams, Director.

SYRACUSE—The R. G. H. Metal Manufacturing Co., 106 South State St., has purchased a site at 108-112 South State St. and plans to build a 3-story plant. Estimated cost, \$25,000. A. E. Star, secretary.

North Carolina

RALEIGH—The International Vegetable Oil Co. will build an addition to its oil plant, here. Estimated cost, \$30,000. W. F. Marsh, manager.

Ohio

CINCINNATI—The Chas. Boldt Paper Mill Co., 5500 Eastern Ave., plans to build a 1-story, 48 x 100-ft. and a 6 x 220-ft. addition to its paper mill. C. Boldt, president.

COLUMBUS—M. Peterman, architect, Rector Building, is receiving bids for the construction of 1- and 2-story addition to the cleaning plant of the Buckeye Cleaning Co., Main St. and Alum Creek.

DAYTON—The Dayton Oxygen & Hydrogen Products Co., 17 B. Annex, has awarded the contract for the construction of a 2-story, 60 x 150-ft. factory on South Broadway, to the Blanchard Building Co., Dayton. Estimated cost, \$45,000.

MARION—J. H. Fair plans to build two buildings, 2-story, each 25 x 30 ft., for dry cleaning plant. P. D. Jacobs, Church St., architect.

MIDDLETOWN—The Gardner-Harvey Paper Co. has awarded the contract for the construction of a 2-story, 35 x 250-ft. paper mill, to Frank H. Smith, Inc., West 3rd St., Dayton. Estimated cost, \$30,000.

SPRINGFIELD—The Ohio Steel Foundry Co., Lagonda Ave. and Gothic St., will build a welding building, garage and research laboratory. Estimated cost, \$25,000.

Oklahoma

ENID—The city plans an election soon to vote on \$100,000 bonds, \$300,000 to be used for waterworks improvements and extensions, and \$175,000 for the construction of a sewage disposal plant, etc. Black & Veatch, Interstate Building, Kansas City, Mo., engineers.

OKLAHOMA CITY—The Hazelrigg Laboratories, incorporated with \$50,000 capital by V. T. Hazelrigg, president, and Dr. J. E. Harbison, 310 Mercantile Building, treasurer, plans to build a plant. Project includes the largest chemical, bacteriological and serological laboratories in the Southwest.

TULSA—The trustees of the Henry Kendall College, Cleveland 7th Sts., are having revised plans prepared for the construction of a gymnasium. Plans include the installation of a filtration plant, etc. C. E. Buchner, chairman.

Oregon

CORVALLIS—The Board of Regents of the State Agricultural College has awarded the contract for the construction of a 2-story, 56 x 220-ft. engineering laboratory on the college campus, to Snook & Travers, Albany, \$69,987. Noted June 15.

Pennsylvania

FULTON—The National Metal & Moulding Co., Fulton Building, Pittsburgh, plans to build a 1-story, 130 x 250-ft. addition to its plant, here.

ALTO—The State Department of Health, Harrisburg, has awarded the contract for constructing and equipping extensions to

the sewage disposal plant at the State Sanitarium for Tuberculosis, near here, to Simpson & Brown, 90 West St., New York City, \$23,031.

PHILADELPHIA—The Keystone Pure Oil Co., Broad St., below Huntington St., has awarded the contract for the construction of a 2-story, 76 x 150-ft. factory, to F. A. Havens, 845 North 19th St. Estimated cost, \$40,000.

PITTSBURGH—The Damascus Bronze Co., 328 South St., plans to build an 80 x 80-ft. addition to its plant.

South Carolina

ANDREWS—The City Council will soon receive bids for laying sewer mains and constructing a sewage disposal plant. Estimated cost, \$50,000. Tomlinson Engineering Co., Loan & Exchange Bank Building, Columbia, engineers.

BATESBURG—The city plans an election July 11, to vote on \$40,000 bonds for the construction of a sewerage system, to include a septic tank, etc.

Tennessee

KNOXVILLE—The Day Pulverizer Co. plans to build a factory addition to its plant, also install machinery in same.

Texas

WICHITA FALLS—The Committee of the Northwest Texas Insane Asylum will soon award the contract for the construction of an administration building at the asylum here, including sewage disposal plant, etc. Total estimated cost, \$350,000. C. H. Page & Bros., Austin National Bank Building, Austin, architect.

Washington

SEATTLE—Dr. J. Wilkins, Cobb Building, has awarded the contract for the construction of a 3-story, 34 x 60 x 70-ft. hospital on 16th Ave. and 3rd St. to P. T. Bratt, 4902 Phinney Ave. Plans include the installation of an X-ray laboratory. Estimated cost, \$55,000. J. R. Nevins, Hoge Building, architect.

West Virginia

CHARLESTON—The Superior Red Granite Co., 313 Kanawha Building, plans to build a granite crushing plant, and is in the market for crushers having a daily capacity of eight cars of granite.

WESTON—The State Board of Control, Charleston, has awarded the contract for the construction of a sewage disposal plant at the Weston State Hospital, here, to C. E. Collins, Drexel Building, Philadelphia, Pa. Estimated cost, \$45,000. Noted June 1.

Wisconsin

CARROLLVILLE (Osten P. O.)—The United States Fertilizer Co., c/o the United States Glee Co., will soon award the contract for the construction of a 2- and 3-story, 67 x 219 and 50 x 50-ft. fertilizing plant. Estimated cost, \$100,000. H. J. Esser, Camp Building, Milwaukee, architect.

GREEN BAY—The Port Howard Paper Co. has awarded the contract for the construction of a 1-story, 49 x 135-ft. factory, to Ludolph Hansen, 114 South Maple St. Estimated cost, \$45,000. Noted April 1.

MILWAUKEE—The Pfister & Vogel Leather Co., Virginia St., has awarded the contract for the construction of a 2-story, 60 x 120-ft. addition to its tannery on Bay View St., to C. A. Kleppe, 1026 1st St. Estimated cost, \$30,000.

TWO RIVERS—The Board of Education will install laboratory equipment in the 3-story, 80 x 155-ft. high school which it plans to build on Main St. Total estimated cost, \$125,000. T. D. Chubb, 109 Dearborn St., Chicago, Ill., architect.

Nova Scotia

TIVERTON—The Digby Fish Meal Co. will soon receive bids for the construction of a 3-story, 60 x 100-ft. factory on Queen St. for the manufacture of fish meal and extraction of oil. Estimated cost, \$25,000.

Ontario

KINGSTON—The Department of Public Works, Ottawa, will soon award the contract for the construction of a sewerage system and disposal works at the Sydenham Hospital, here. Estimated cost, \$100,000.

KINGSTON—The Municipal Council plans to expend \$30,000 for new purifiers, \$10,000 for liners and \$10,000 for generators to be installed in the gas plant.

OWEN SOUND—J. Legate, chairman of the Utilities Commission will soon award the contract for the construction of a concrete slow sand filter at No. 1 Spring, Derby Township. Estimated cost, \$35,000.

OWEN SOUND—The Utilities Commission is receiving bids for furnishing a slow sand filter. R. McDowell, engineer.

ST. CATHERINES—The city plans to build sanitary sewers and a sewage disposal plant. Estimated cost, \$50,000. W. P. Near, City Hall, engineer.

Quebec

GRANBY—The Miner Rubber Co., 72 St. Peter St., has awarded the contract for the construction of a rubber factory to the Dominion Bridge Co., 235 Beaver Hall Hill, Montreal. Estimated cost, \$35,000.

MONTREAL—The Scot-Canadian Magazine Co., Ltd., Power Building, plans to build a plant on Shawinigan St. Estimated cost, \$350,000.

SALBERT—The Chicoutimi Paper & Pulp Co., Chicoutimi, is having plans prepared by L. Lamontagne, architect, Chicoutimi, for the construction of a factory. Estimated cost, \$75,000.

Industrial Notes

ARTHUR D. LITTLE, Inc., of Cambridge, Mass., has designed and is installing improvements and enlargements in the plant of the Minute Tapioca Co. at Orange, Mass.

THE NATIONAL REDUCTION CO. is building a large rosin and turpentine plant at Calverton, Ala., designed and erected by Arthur D. Little, Inc., of Cambridge, Mass.

THE NEW YORK TESTING LABORATORIES have been organized by Messrs. L. R. Seidel, G. B. Jack, Jr., and H. H. Geist, formerly chief metallurgist and chief chemist respectively of the Wright-Martin Aircraft Corp. The laboratories are at 354 Mulberry St., Newark, N. J., and the New York office is established at 74-80 Washington St. In addition to chemical and physical testing and microphotography, this organization is specializing in the source inspection of materials, and as consultant in smelting, foundry, drop-forging and heat-treating practices and the metallurgical investigation of shop troubles.

THE CARRIER ENGINEERING CORP., announces that Mr. E. P. Heckel has been made vice-president of the corporation and transferred from New York to Chicago as Western manager. Mr. A. E. Stacey, former Western manager, has been transferred to New York as head of the department of research and development.

BECKMAN & LINDEN CORP., San Francisco, Cal., has installed a 100-kw. single-phase electric furnace for commercial testing and research on the electric smelting possibilities of the Pacific Coast region.

THE METAL & THERMIT CORPORATION, New York, has recently completed the largest marine weld ever recorded, on the east steel sternframe of the huge U. S. Army Transport Northern Pacific. The section welded was entirely broken through as a result of the strain to which the frame was subjected when this transport, laden with homeward-bound troops, ran aground on Jan. 2, 1919, in a dense fog off Fire Island, New York. The weld, 1400 lb. of thermite for the chemical production of the necessary amount of molten steel, and was made without removing the casting from the ship.

CHEMICAL FOUNDATION, INC., has opened offices at 31 Fulton St., New York City and is ready to discuss the issuance of licenses for the various German chemical and metallurgical patent rights. Licenses must be held by American and possess ability and equipment to manufacture under the license.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its 1919 convention in Philadelphia, Sept. 29 to Oct. 4.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its Fall meeting in Chicago, Ill., Sept. 22-27.

THE AMERICAN STEEL TRADERS' SOCIETY will hold its first annual convention in Chicago, Ill., Sept. 22-27.

THE FIFTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in Chicago, Ill., Sept. 22-27, inclusive.

THE INSTITUTE OF METALS DIVISION of the A. I. M. E. will hold its next meeting in Philadelphia, Pa., Sept. 29 to Oct. 4.

THE INSTITUTE OF METALS will hold its Autumn meeting in Sheffield, England, Sept. 23-25.

THE INTERALLIED CHEMICAL CONFEDERATION will hold its next meeting in London, July 15-18, 1919.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its Fall meeting in Chicago, Ill., from Sept. 24 to 27.

THE SOCIETY OF CHEMICAL INDUSTRY will hold its annual general meeting in London July 15-18, 1919.

The Season of Tariff Hearings

ELSEWHERE in this issue we report some of the hearings recently held in Washington before the Ways and Means Committee of the House of Representatives on bills designed to derive revenue for the Government and encourage the domestic production of certain minerals and mineral products. In other words, a new tariff is about to be framed, and proponents of tariff protection for certain industries have been active in presenting their claims. Tungsten, magnesite, potash, zinc, dyes, optical glass, chemical glass and laboratory apparatus are among the items for which protective duties are asked. The reasons are various, ranging from the protection of key industries to the loyal support of domestic enterprises that will free us from German domination. In the main they are all good.

A reading of the arguments is suggestive of the delicate problems that Congress will be called upon to solve. Shall we protect one industry when the effect will be to levy tribute on several others that would thrive better under free trade? On the one hand we have the infant industry, in this case possibly a war industry, clamoring for protection and urging deliverance from foreign, possibly German, bondage. On the other hand, we find consumers who prefer a foreign product for real or fancied superiority and who object to being taxed to support a domestic industry. Truly the wisdom of a Solomon is demanded. For our own part we have previously expressed an opinion to the effect that industries asking tariff protection must be on a sound economic basis, with good business direction and technical control. We cannot look with favor on substituting a tariff for industrial inferiority or lack of technical skill; nor, on the other hand, do we believe that a little foreign competition will be harmful. In this respect we like the attitude of the tungsten producers, who say frankly that the duty they ask will still permit foreign ore to enter to the extent of half our domestic needs, while it will also act as a stabilizer of the industry at home.

In the case of scientific glassware and apparatus we confess to an abhorrence of the duty-free favor granted our colleges and universities, because it has made German products better known than American; and for the further reason that continuance of the plan affords an entering wedge for German propaganda among our students. On only two occasions, after the Mexican and Civil wars, have our revenue requirements been such as to make it necessary to exact duty from the beggarly funds of our colleges. Today the question is quite different. Freight charges on this class of material are small compared to values. Eighty to 90 per cent of the

cost of production is for labor, and the low-wage countries will find these industries peculiarly their own. In Germany there are over 500 firms manufacturing scientific apparatus, employing thousands of instrument makers and technical men. Less than one-tenth this number is credited to the United States even after four years of favorable development. We cannot look with favor on the subordination of these industries at home merely to favor the colleges. We believe our educational institutions want to stand on their own feet and pay their way. We believe that students and faculty alike will scorn the savings that might be effected by taking the sop thrown by foreign competitors. Sixty per cent duty may be needed, and domestic goods may cost our colleges \$2,000,000 additional each year, but this may be regarded as insurance against pitiful dependence on an undesirable neighbor.

A New Philosophy Of Chemistry and Matter

ELSEWHERE we print in this issue Mr. HENDRICK'S paper on the Langmuir postulates, which is designed as an introduction to the subject and not as a complete exposition of it. The changes proposed in regard to the conception of molecules and valence are so radically different from those with which we are familiar that it is hard to forego the natural disposition to oppose them. It requires an easy familiarity to make use of the postulates in thinking of chemical reactions and the resultant bodies, and we believe that in time it will be possible to approach them with greater clarity than at present. The series which we present contains but eight, whereas in Dr. LANGMUIR'S original paper there were eleven. In his later papers they will appear in the present form—for which we are indebted to him—and we hope that this, too, will be simplified as time goes on.

The promise, as indicated in the amazing similarities of physical qualities between bodies apparently unrelated except that they are held to be identical in their atomic or molecular structures, is too great to be passed over without careful observation and scrutiny. If by applying the octet rule and determining the covalence of each atom we may determine the physical nature of a body even before it is synthesized, we have, without doubt, an instrument of great value in chemical practice. But it may even be determined, according to Dr. LANGMUIR'S theories, whether unknown substances will have color or not. Again, it has always wrenched us to consider that, among metallic salts, for instance, no molecules are formed, but that they build a lattice of alternate positive and negative ions which are held together by electrostatic force rather than by bonds. Nevertheless this conclusion, which is wholly in accord

with the work of the BRAGGS, now appears reasonable, except in the shade of prejudice; and in the end we seem to obtain from it a remarkably practical working concept of chemical processes. It is, however, unfamiliar—and it is a normal human reaction to deny that which is unfamiliar.

Our colleague the ever urbane editor of *Scientific Monthly* evidently feels that way. After listening to a presentation of the subject by its author during the Convocation Week of the American Association for the Advancement of Science, in Washington, he says, referring to the addresses of Professor BREASTED of Chicago and DR. LANGMUIR of Schenectady, that they (the addresses) "might lead to the inquiry why a student of Mexican archaeology is eligible to membership in the [National] Academy but not a student of Egyptian archaeology," and "why a metaphysician who calls himself a chemist is eligible, but not one who calls himself a student of philosophy."

As the author of our paper intimates, DR. LANGMUIR is almost resentful of metaphysics in connection with comprehensible and concrete facts. He does deduce the rule that electrons tend to gather in pairs and octets about positive charges, but if this be metaphysics then so is valence, and so also is the law of definite proportions.

WERNER's theory of secondary valence, while not wholly in accord with the Langmuir postulates, is illuminated by the octet rule. WERNER's observations are confirmed, but they are explained by a different method. Neither this feature, however, nor several others of marked importance, are touched upon in our present article. Our immediate business is of an introductory nature.

Are We Engineers or Are We Economists?

ASPECTACLE of high wages together with a surplus of labor, high commodity prices together with a small turnover, extreme spread between wholesale and retail prices and yet moderate purchasing by the ultimate consumer, cold storage and granaries bursting with foodstuffs yet meat and dairy products beyond the reach of ordinary purses—this spectacle certainly holds puzzling inconsistencies to the thoughtful observer. The times are so badly out of joint that his personal experience cannot bridge the gap, and yet he is confronted with the insistent question: "What can I do about it?"

What is to be done? Economists who hold the front of the stage assure us that nothing can be done except grin and bear it; make up your mind to buy what you need and pay the price, say they. "Opportunity is here!" shouts the publicist. "The shelves of the world are bare." True, indeed, but has poor Mother HUBBARD a bare purse as well as a hungry dog?

Students of economic life make much of the so-called law of supply and demand, and its many adaptations. Thus—we have recently seen an enormous inflation in currency and credit, the actual amount of usable goods has probably decreased, prices therefore have gone up with the volume of money available. This really seems a good definition of high prices rather than an explanation of how they came about—in other words, the fact that we have a huge gold reserve is not the immediate reason an Oregon horticulturist asks and gets 13 cents for prunes he gladly sold for 5 a few short years ago. On the face of it there seems to be a human

as well as a material element in prices. We are inclined to think—not being economists, merely engineers—that some influential economists have overlooked a profound determining factor in price levels, and this factor is that a price is determined not only by the available supply of needed goods and the total amount of purchasing power in existence, but also in large measure by how badly the individual purchaser thinks he needs and desires the thing, the availability of acceptable substitutes, and the credit or money he actually possesses. When butter goes beyond a certain price, he doesn't buy as much as he needs.

Thus one arrives at the psychological factor, at once ignored and acknowledged by publicists—ignored in arguing for permanence of high prices; acknowledged in their campaign to create a "purchasing state-of-mind." Some even go so far as to print in black headlines "All Price Revisions Will Be Upward!" As a general, long-time trend, yes; as an immediate tendency, by no means! Do they mean that the glaring inefficiency of management, labor and process which was so shamelessly condoned during war time cannot be improved? Do they mean that the exorbitant capital profits, amounting in many cases to the total pre-war cost of the commodity, cannot be eliminated? Do they mean that \$12 shall be maintained as a price for a shoe costing \$6 simply because the raw material, manufacture and sale are so closely controlled that the higher price can be demanded?

Historical economists are fond of pointing out the rise in commodities which accompanied and immediately followed the four recent wars in justification of their stand that the present price levels will be permanent. Perhaps the analogy is correct. But they fail to add a note explaining the drop in commodities which actually occurred sooner or later. Apparently if it be true that high prices are due to inflation, and inflation is due to the waste of war, it certainly follows that high prices can be cut by reducing waste. Here, indeed, is where the engineer can help—at least he can be of vital force instead of an apologist. The human element is again overlooked when no mention is made of the reason—cited solely as an instance—why pig iron should drop from \$53 just after the Franco-Prussian war to \$9 just before the Spanish-American war. That was technology! Not only bigger blast-furnaces, but better chemistry and metallurgy, better transportation, better electrical and mechanical engineering, and the application of iron and steel to thousands of everyday uses!

Enough has been said to indicate the extreme complexity of the economic situation. Economic laws are not deducible to mathematical formulæ as are those of gravitation, because the human element—that most complex of variables—enters. Engineers are treading on *terra incognita* and are in danger of being bogged when they make pronouncements based on economics; far better it would be to insist at all times and places upon the extreme desirability of reducing costs by scientific technological management. Here we can speak with authority, candidly acknowledging in all our dealings the close relationship between the human and the material, the worker and the machine.

Reduce waste, perfect processes, increase efficiency of men and machines, lower costs by increasing the volume of production, raise the standard of living by making it possible for the common citizen to purchase good products, and engineers can then rest assured that

their work has been well done, since it has vastly increased the sum total of human happiness. That is really the end of it all!

A Phase of the Flotation Decision

IN OUR digest of the Supreme Court's decision in the case of *Minerals Separation vs. Butte & Superior*, we doubt if we emphasized sufficiently those words of the Court's opinion in which it defines the scope of *Minerals Separation's* right as "limited to the means they have devised and described as constituting the process." Granting the plaintiff its right to the process when oil is used in a fraction of one per cent on the ore, the Court nevertheless holds that the patentees discovered the *process* and not the *result*, and limits the process to the *means* disclosed. Evidently if the same result can be attained by some other means, the industry still has the prospect of working with an economical use of oil. In our judgment the bubble-column process, commonly spoken of as the pneumatic-cell process, is outside the means disclosed by *Minerals Separation* in patent 835,120 and is therefore open to use with an economical quantity of oil, and without infringement of the patent referred to. This may have a profound influence on future flotation practice.

The Determination Of Steel Prices

THE steel market has for many years presented an interesting psychological study. There has been some evidence of the working of the much mentioned law of supply and demand, but after all the steel market has been made more by psychological than by physical influences. It has been a matter not only of how the minds of producers react to certain influences but also of how the minds of buyers react.

In most of the steel price advancing movements of the past fifteen years the co-operation of buyers has been necessary. It was a case of one advance bringing on another. The buyer, seeing the market exhibiting strength by advancing, would place contracts for forward delivery for additional tonnages and when this buying had encouraged the mills to make another advance the buyer would buy again, thus furnishing the basis whereby prices could be advanced upon him a third time, and so on.

As to the sellers, the mental attitude has influenced conduct, though not always in the same way. In the decade of the 1890's, when the mild-steel business was young as the successor to the wrought-iron business, the mental attitude of the producer was frequently not so much that of endeavoring to secure orders as of preventing his competitor from securing them. It was a common practice to induce a consumer to place a contract for material he did not expect to need, with the idea that he might possibly find occasion to use the material, and then the seller who had seen him first would receive the specifications. The fundamental principle was that of undermining the competitor's business rather than of building up one's own business. The pools and associations that thrived on paper were patronized by producers not so much because they individually expected to adhere to the agreements as because hopes were entertained that others would do so, and thus lose orders.

Subsequently the psychology of producers changed.

Passing over a few years, first of the existence of the combinations preceding the Steel Corporation and then the earliest years of the Steel Corporation itself, there began a period in which the idea of domination was definitely and actively renounced. The larger of the individual manufacturers in the early years of steel-making sought domination as the only safe position. The Steel Corporation, on the contrary, recognized that in the long run domination would be suicidal because neither the law nor the public would give it countenance. Markets, however, must be made through the operation of one influence or another. They do not spring from nothing. Markets are made by men, and the question is only as to the influences to which men allow their minds to react. The influence may be the relation between the tonnage that is likely to be consumed and the tonnage that can be produced, or the mental attitude of buyers, or the mental attitude the producer believes his competitors occupy.

The Great War sent steel prices to undreamed-of levels, and then Government control intervened. At the close of the war demand dropped to small proportions. Here was an upheaval or succession of upheavals which one would naturally expect to leave the market in a highly unsettled state, capable of wide fluctuations. A practical question is whether, after so great a disturbance, steel prices are going to fluctuate more or less during the next half dozen years than they did in the decade before the war. After such a disturbance wider fluctuations than usual might reasonably be expected, but having in mind the psychological influences at work one might conclude that the clearly apparent danger of a widely fluctuating market would induce the men who make the markets, irrespective of whether their decisions are individual or collective, to take special pains to prevent such wide fluctuations in prices.

Much has occurred that is suggestive of the possibility that eventually the Federal Government will be largely instrumental in the formulation of steel-market prices. The Federal Trade Commission was organized in March, 1915, and has had more or less to say about steel prices, particularly during the war. The Supreme Court is to decide the Government's dissolution suit against the Steel Corporation, which gives that branch of the Government a vital interest in the subject. It will, in a measure, pass upon the propriety of the steel prices that have obtained during a large part of the Steel Corporation's life, from the viewpoint of the public interest. Last February the Department of Commerce formed the Industrial Board for the purpose of deflating or stabilizing steel prices, and while the Industrial Board had rather an ill-starred and brief career the fact is not modified that there was a desire in Washington that such an organization should exist and function.

Even nearer to the point is the fact that when the organized steel consumers of the Chicago district recently urged that Chicago be established as a separate basing point for steel products, thus reducing the previously universal scope of the Pittsburgh basis, the steel producers proposed that the matter be laid before the Federal Trade Commission. If it is proper that the Commission should decide what prices should obtain in the Chicago district relative to Pittsburgh basis prices, it is no great step for it to have a voice in determining what prices should obtain at Pittsburgh relative to industrial conditions.

Readers' Views and Comments

Fusibility of Ash From Pennsylvania Coals

To the Editor of *Chemical & Metallurgical Engineering*

SIR: I have read with much interest the paper on "Fusibility of Ash From Pennsylvania Coals," which appeared in your issue of June 15, 1919. Messrs. Selvig and Fieldner make one statement in that paper which I feel should not pass without some comment and qualification. The last paragraph on page 629 reads:

"The ash from the anthracite region of Pennsylvania is very refractory, coming in Class I. The softening temperature in practically every instance is above 3000 deg. F."

Now this statement is true in so far as it covers the ashes of coals tested and reported in the paper by Selvig and Fieldner, but the fact remains that ashes from certain anthracite coals have not been included in the published results. In order that the statement made by the authors may not mislead any one into regarding all anthracite coal ash as highly refractory, it has been thought desirable to submit some data on work done in this laboratory.

In a paper on "Chemistry in Coal Mining," published in the Aug. 19, 1916, issue of *Coal Age*, a table was given showing fusing temperatures and analyses of ashes of coals from different mines. The content of alkalies in the ashes was not determined, and any titanium dioxide was included in the percentage of aluminum oxide. The data are given in Table 1.

This table shows that the ash of some anthracite coals fused between 2210 and 2282 deg. F., whereas the ash from other anthracite coals did not fuse at a temperature of 2570 deg. F., this temperature being the highest reached in the tests made at that time.

Later work in which higher temperatures were reached has shown practically the same results. The ashes from Shamokin, Locust Mountain and Hard White Ash coals have, in general, shown high fusing temperatures, mostly above 2600 deg. F. The ashes from Lorberry coals have shown somewhat lower fusing temperatures. The ashes from Lykens Valley coals have shown very much lower fusing temperatures, some such ashes fusing even below 2282 deg. F.

This lower fusing temperature seems to be coincident with relatively higher content of calcium oxide and sulphuric anhydride in the ash of the coal. The sulphur content of the coal itself, in the case of Lykens Valley coals, is very low, but much of this sulphur is left in the ash after burning, possibly in the form of cal-

cium sulphate. Further work on this problem is highly desirable.

It might be remarked, in passing, that while the ash from Lykens Valley coal has a low fusing temperature, yet the ash from bony coal or slate has a fusing temperature above 2600 deg. F.

Unfortunately, our tests on coal ashes were made in a rather crude way. The ashes, molded into form of small cones, were heated in a muffle furnace over a coke fire, the temperature being determined by comparison with Seger pyrometric cones. The atmosphere, if we may judge from the appearance or color of the ash cones, was an oxidizing one.

We do think, however, that our work is of considerable value, at least from a comparative standpoint, and we submit the above statements as information modifying some of the conclusions reached by Selvig and Fieldner.

Tin in Bolivia

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—A study of the tin deposits in the world shows that Bolivia occupied a very prominent position, not only on account of the nature of the minerals found in its mountains, but also because of the wealth of its ore deposits. If we consider the various sources of tin, we find the most important to be as follows: The peninsula of Malacca, Banka, Billiton, Sumatra, Siam, New South Wales, Australia, Tasmania, New Zealand, Cornwall, Transvaal, Japan, Finland, China, Korea, Siberia. Other deposits of less importance in central Europe are in Spain, Portugal, France, Italy, Scotland, Ireland and the well-known deposits in Bohemia; some in the United States and Alaska; and none in South America except in Bolivia, which has gradually become second in importance as a producer of tin.

Nevertheless the tin deposits of Bolivia are very little known and up to date only a comparatively small section has been exploited, and that is the region which is richest and possesses minerals of the most desirable composition. In a word, it can be said that the only mines operated in Bolivia are those which contain extraordinary wealth. In the meantime in my opinion the real future of Bolivian tin industry lies in those deposits of lower grade which up to the present time have not been touched.

The country contains extensive deposits of tin in the principal mountain chains; and in some of the rivers

which rise in some of these mountains there are large alluvial deposits of tin which have never been exploited. In order to produce the metal in large quantities at a profit it would be necessary only to install large concentrating plants that would handle thousands of tons per day. To accomplish this it would be necessary first to interest American capitalists to make a study of the country and invest in Bolivia the large capital that would be required to make these installations.

I have always been surprised at the fact that the United States, itself the largest consumer of tin in the world, has never made the slightest effort to own its mines; and it is quite surprising that the United States has never taken notice of Bolivia, the country richest in this mineral, where it would be possible to make a development sufficiently extraordinary to supply the total consumption of North America.

Recently Mr. William S. Kies, vice-president of the American International Corporation of New York, visited Bolivia. I have had the pleasure of several talks with him on the subject of tin production and have called his attention to the fact that his country should make a study of Bolivia from the point of view of developing tin mines on a large scale. I trust that this may serve as a starting point for a business development that will be of mutual benefit to both nations.

La Paz, Bolivia.

JUAN M. REYES.

Copper in Slags

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—In the review of our article on Slags published in the last issue of your journal, there is a numerical error in the first column. You say that analyses of blast-furnace and reverberatory slags showed an average residue of 0.7 per cent Cu insoluble in AgNO_3 , with an average deviation of only 0.11 per cent.

The figures should be 0.147 per cent instead of 0.7 per cent, and the average deviation should be 0.011 per cent.

The Analysis of Red Lead

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—Referring to the above heading in your issue of March 15, I have looked up the article published in the *Journal of Industrial and Engineering Chemistry* of March, 1916, and find that Mr. Schaeffer, in his application to the analysis of red lead, failed to give me credit for a prior application of the lead peroxide-hydrogen peroxide-potassium permanganate reactions in dilute nitric acid solution for determining lead (Ericson's lead method), although I have published several papers on the subject, viz.:

"A New Volumetric Method for the Determination of Lead," *Journal of the American Chemical Society*, September, 1904.

Later another paper on its application to spelter analysis entitled "A New Technical Method of Spelter Analysis" published in the *Journal of Industrial and Engineering Chemistry*, May, 1913. Other papers were published in the *Engineering and Mining Journal* at various times.

I have used this method daily (peroxidizing the lead by means of ammonium persulphate in ammoniacal solution, filtering, dissolving in a known excess of hydrogen peroxide solution, and titrating the excess by

standard potassium permanganate) for a dozen years in the zinc industry and on Joplin ores principally, so it is strange that Mr. Schaeffer should not have heard about it. Several Joplin chemists have been acquainted with it, and some in the lead industry.

Mr. Schaeffer deserves credit for his ingenious application of my method to the analysis of red lead, but should have given me due credit.

ERIC JOHN ERICSON.

Philadelphia Meeting of the American Chemical Society

THE annual meeting of the American Chemical Society will be held at the Bellevue-Stratford Hotel, Philadelphia, Sept. 2 to 6, 1919. Unusual interest will center in this meeting on account of the consideration of important problems confronting the chemical industry. The adaptation to peace purposes of plants erected primarily for the production of explosives and munitions will be one of the important subjects under discussion. In this connection the Hon. Newton D. Baker, Secretary of War, has promised to make an address at the general meeting.

The division of industrial chemists and chemical engineering will have a symposium on refractories which will interest all who are concerned with furnace linings and processes where heat-resistance is required. Another subject to be considered by this division is the revision of the patent law, with particular reference to the charge of a renewal fee to prevent so-called patent pirates from keeping claims on file indefinitely without intention of developing the patent. A representative of the Patent Office is expected to be present and an invitation has also been sent to A. Mitchell Palmer, Attorney-General, formerly Alien Property Custodian.

The newly constituted rubber section is expected to have a program of considerable interest.

The Philadelphia section is making arrangements for entertainment of visitors, and it is expected that all of the large chemical plants in Philadelphia and vicinity will be open. A boat trip on the Delaware has been arranged, and a visit will be made to the Hog Island Shipyard and the League Island Navy Yard. An automobile trip to Valley Forge and a smoker will be features of the entertainment.

The Philadelphia local section urges all who are able to attend the meeting to reserve hotel accommodations as soon as possible.

American Steel Treaters' Society to Hold Convention

In planning the first annual convention, to be held at the 7th Regiment Armory in Chicago from Sept. 22 to 27, inclusive, the American Steel Treaters' Society has decided to include an exhibit of freaks which have resulted from heat treatment. The members have been asked to contribute examples of tools that have, in hardening or tempering, acted contrary to all theory and ordinary practice or that have cracked, expanded, contracted, warped, etc., in an inexplicable manner. Other odd occurrences in heat treating iron and ferrous alloys will be shown. It is hoped that the interest aroused in this exhibit will result in an exchange of explanations and theories which will aid materially in increasing our understanding of the mechanism of heat treating.

Tariff Hearings on Tungsten

THE proposed tariff on tungsten ores and products as embodied in the Timberlake bill (H. R. 4437) was the subject of hearings before the Committee on Ways and Means, House of Representatives, June 13, 14 and 17, 1919. The bill provides for duties on crude tungsten ores and concentrates of \$10 per unit WO_3 , and on metallic tungsten, ferrotungsten, tungstic acid, salts of tungsten, tungsten steel and other tungsten products of \$1 per lb. of tungsten contained therein. The purpose of the tariff is to stabilize the tungsten industry in this country and to prevent the dumping of foreign tungsten ore from countries where cheap labor prevails.

It was brought out that the domestic requirements for the next few years may be estimated conservatively at 5000 to 7500 tons of 60 per cent concentrates per year. Domestic production has provided about 60 per cent of our needs, the balance being imported. One witness was of the opinion that the proposed duty would still allow 50 per cent of the tungsten used in the United States to be imported. He stated that it was not contemplated that foreign ore would be shut out.

Evidence was introduced to show that Asiatic ore could be delivered in this country at \$7 per unit and still afford the Asiatic miner a profit. Labor costs for coolies were reported as 40 to 47c. per day for men and 20 to 27c. for women and children. Ore from Bolivia, however, during the war was delivered at New York for between \$20 and \$22 per unit, though probably it could now be delivered at \$16 to \$18 a unit. The cost of producing tungsten in the United States is impossible to estimate with accuracy. It may be great or small, varying with the ore body and the cost of development. As a consequence costs are so widely different that any attempt to correlate them is fruitless. In Colorado in 1918 costs were estimated to range from \$15 to \$33 per unit, with an average of approximately \$20. California costs are lower, but the U. S. Tariff Commission estimates that one-half of the domestic output is produced at a cost from \$10 to \$15 per unit and that the remainder costs from \$15 to \$25 per unit, averaging, say, \$20.

The status of the tungsten industry in the United States is one of complete inactivity if we except operation of one mine in Nevada. Since the declaration of armistice all other properties have been closed. The Colorado producers showed that some properties were dismantled and that millions of dollars worth of property was affording no return on the investment. Cost of producing in this district has been increasing with the depth of the mines and the reduced grade of the ore. At the outbreak of the war the price of tungsten ranged from \$6 to \$7 per unit and the industry was paralyzed. War demand caused prices to soar as high as \$90 per unit early in 1916. Later the price fell off to \$20 or \$25 per unit. When the price fell to \$17 per unit all of the mines closed. This figure therefore was considered the dead line for all except a very few American producers, and it was the opinion of one witness that the figure represented absolute minimum cost of production.

Witnesses expressed their belief that a duty of \$10 per unit on tungsten ores and concentrates would enable domestic producers to develop tungsten resources so that national requirements could be met at any time.

It was felt also that \$10 per unit would practically cover the difference between the average cost of production in the United States and foreign fields. It was very clearly brought out that *ad valorem* duties were inapplicable to tungsten ores because they were simply an invitation to foreign exporters to declare a low valuation and thereby pay a low duty.

Zinc Ores and the Tariff

THE Joplin district zinc ore producers were represented before the House Committee on Ways and Means at a hearing held June 18, 1919. Paul A. Ewert, Otto Ruhl and E. B. Howard, Representative from Oklahoma, submitted testimony and exhibits to support the contention of the zinc-ore producers that a specific import duty of 2c. per lb. of zinc in ores containing over 25 per cent zinc was necessary to maintain the zinc mining industry in the Joplin district. The importation from Mexico of ores that were produced at a low cost, due to cheap labor, has practically closed the zinc mines in Missouri and Oklahoma.

The average cost of producing 60 per cent concentrates in the Joplin district during the first part of 1919 has been between \$45 and \$55 per ton, depending upon local conditions, whereas the average declared valuation of Mexican 30 per cent ore for the first three months of this year was \$9.42. The cost of producing 1 lb. of zinc in Joplin concentrates is therefore about 37c. and from Mexican ore 1.5c. The producers therefore reason that the 2c. per lb. specific duty is justified.

The larger quantities imported during the war period came from Australia, Canada and Mexico. Table I shows the amounts. Table II shows the declared value of imported ore per ton compared with the average base price of Joplin zinc ore for same periods.

TABLE I. ZINC CONTENT OF IMPORTED ORE

	1914	1915	1916	1917	1918
Australia.....		11,130	56,726	23,237	789
Canada.....	4,345	4,040	8,092	5,540	6,300
Mexico.....	2,895	15,365	34,805	54,154	28,671

TABLE II.—DECLARED VALUE IMPORTED ORE PER TON COMPARED WITH AVERAGE BASE PRICE JOPLIN ZINC ORE FOR SAME PERIODS

Year Ending June 30	Long Tons (2,240 Lb.)	Value	Value, Short Tons ¹	Value, Joplin Zinc Ore
1914.....	18,280	\$13.70	\$12.23	\$39.79
1915.....	79,814	22.77	20.33	54.16
1916.....	291,264	32.32	28.77	92.78
1917.....	262,767	28.57	25.50	73.57
1918.....	102,234	24.44	21.82	58.30

¹ Values of short tons of 2,000 lb. are computed in order to compare with Joplin ores, given in short tons.

All imported ore has been subject to a 10 per cent *ad valorem* duty. It was brought out in the hearing that the value to which the *ad valorem* duty is applied was furnished by the exporter and represented his valuation of the ore for export and at the port of shipment. There has been a large difference in the actual valuation at port of entry and this figure. It was brought out that in the case of Germany before the war there were two valuations of zinc ore—one for home consumption and the other for export.

The method adopted by the Treasury Department for ascertaining the value of zinc in imported ore arriving in the United States is as follows:

(1) From the ascertained assay deduct 8 units for sulphide and 6 units for non-sulphide ores. The re-

remainder will represent percentage of recoverable zinc in the ore, which multiplied by 2000 will give the number of pounds of zinc recoverable from a ton of ore.

(2) Multiply the result as above ascertained by the average price of prime Western spelter at East St. Louis for the week in which the ore was exported; that is, the week including the date of sailing of the ship or day the car leaves the foreign country. This will give the gross value of the zinc in the ore at the time of its exportation.

(3) Deduct from the gross value of the zinc in the ore as above ascertained the following:

(a) The freight actually paid from the foreign mine to the domestic smelter receiving same in the U. S.

(b) The insurance actually paid.

(c) The actual shipping charges.

(d) Foreign export duties and charges, if any.

(e) Treatment charge (as explained in par. 4).

(f) Penalties for iron (as stipulated in par. 5).

(g) Duty on lead contents, if any.

(h) Duty on zinc.

(4) *Treatment charge.* (c) For sulphide ores the treatment charge will be ascertained as follows: From the value of the recoverable spelter in a ton of 2000 lb. medium grade Joplin sulphide ore, 60 per cent base, deduct the average of the quoted prices for such ore and \$1.50 per ton of 2000 lb. as representing the average freight on Joplin ores from Joplin, Mo., to common Kansas smelting points.

(b) For non-sulphide ores the treatment charge will be ascertained as follows: From the value of the recoverable spelter in a ton of 2000 lb. of 40 per cent calamine ore deduct the average of the quoted prices for such ore and \$1.50 per ton of 2000 lb. as representing the average freight paid from Joplin, Mo., to common Kansas smelting points.

(5) *Penalties.* On iron ore deduct penalties as follows: \$1 on each unit of iron in excess of 1 per cent up to and including 6 per cent; \$0.50 per unit on each unit of iron in excess of 6 per cent up to and including 12 per cent; \$0.25 for each unit of iron in excess of 12 per cent.

(6) The average market price of Joplin zinc ore and prime Western spelter to be taken in accordance with quotations contained in the *Engineering and Mining Journal* for the calendar week including the date of the sailing of the ship or day the car leaves the foreign country.

(7) Recoverable spelter, wherever that term is used in this memorandum, means for sulphide ores the assay minus eight units, and for non-sulphide ores the assay minus six units.

Congressional Hearings on Patent Office Bills

The House Committee on Patents began public hearings on July 9 on three bills relating to the Patent Office. One of these bills proposes to establish a United States Court of Appeals. The second bill would reorganize the Patent Office, remove it from the control of the Department of the Interior, and create an independent bureau to be known as the Patent and Trade Mark Office. The third measure proposes to revise the salaries and create additional department heads in the patent service. All three measures are fostered by the National Research Council.

One of the first to testify before the committee, of which Representative Nolan is chairman, was Fred T. Fish of Boston, a patent attorney, who urged the separation of the Patent Office from the Department of the Interior. Many other patent attorneys and experts are expected to present arguments to the committee, and the presentation of arguments has been placed in the hands of Mr. Prindell, secretary of the National Research Council.

It is understood that the committee is willing to hear anyone interested, and that it reserves to itself the right to amend the bills which were drawn by the National Research Council.

War Trade Board Transferred to State Department

Pursuant to an executive order signed by the President on May 12, 1919, the present personnel, duties, powers, functions and records of the War Trade Board have been transferred to the Department of State as of July 1, 1919.

This transfer will not affect or inconvenience the exporting and importing public in any way. The functions of the War Trade Board will continue to be performed by the present personnel in the building at Twentieth and C Streets, Washington, D. C.

All licenses will continue to be issued in the name of the War Trade Board, and all applications for licenses, and all correspondence pertaining to the activities of the War Trade Board, now assumed by the Department of State, should be addressed to the War Trade Board as heretofore.

The War Trade Board Section of the Department of State announces that it will issue licenses permitting the importation, on or after Sept. 1, 1919, of pig tin and all metal alloys containing tin, including tin drosses, tin oxides, solder drosses, type metals, anti-friction metals, waste metals, and other metals containing tin, from points other than points of origin and without reference to the date of shipment.

Columbia University Fellowships

The General Bakelite Co. has provided the funds for an industrial fellowship in the department of chemical engineering of Columbia University. This fellowship differs from the general type of industrial fellowships in that, in addition to the amounts paid to the fellow and for the chemicals and apparatus used by the fellow, a sum is paid to the university to compensate it for the use of the laboratories and other facilities used by the worker. A further difference is that no time or other limitation is put upon the publication of the results of the investigation. Mr. Mortimer Harvey has been appointed to this fellowship for 1919-20.

Mr. George Barsky has been appointed to the Bridgman fellowship (\$1500) at Columbia University for the year 1919-20. He will work in the department of chemical engineering with Prof. McKee on the utilization of the waste liquor from sulphite pulp mills. Mr. Barsky received the degree of Chemical Engineer in 1918 from Columbia University.

Investigating Water Resources in Canada.—The Canadian Government decided in Council held on April 19, 1919, to investigate and develop the water-power resources of the Dominion.

Quicksilver Produced in the U. S. in First Quarter of 1919

ACCORDING to figures compiled by F. L. Ransome of the United States Geological Survey, about 5960 flasks of quicksilver of 75 lb. net was produced in the United States from Jan. 1 to March 31, 1919. Returns from 23 productive mines gave a total of 5924 flasks, and it is estimated that 36 flasks was obtained from two or three small mines in California and Oregon whose operators were not heard from. Of the 5960 flasks produced, 4023 are credited to California, 1698 to Texas, 193 to Oregon and 46 to Nevada. No production was reported from Idaho or Arizona.

The quicksilver reported on hand at the mines or in transit to market at the end of the quarter amounted to 4419 flasks.

As was expected, the output during the first quarter of 1919 was considerably less than that during the first quarter of 1918, which was 8764 flasks. The decrease was 2804 flasks. The unsold stocks at the end of the first quarter of 1918 amounted to 2800 flasks, or 1619 flasks less than at the end of the first quarter of 1919.

The average monthly price of quicksilver in San Francisco, as quoted in the *Mining and Scientific Press*, for January was \$103.75, for February \$90, and for March \$72.80.

The falling off in production is the result of a combination of causes, chief among which were a lessened demand for the metal and a consequent downward trend of prices, the continued high cost of labor and supplies, and the curtailment of underground exploration and development during the war, when energy was directed chiefly to immediate production. The price of quicksilver, compared with the prices that prevailed before the war, was still high at the end of the quarter, but not high enough to offset the general decrease in the tenor of the ore immediately available and the high cost of mining and treatment.

The Examination of Materials by X-Rays

A joint meeting of the Faraday and the Röntgen Societies was held April 29, 1919, in the rooms of the Royal Society. The chairman, Sir Robert Hadfield, in introducing the discussion, expressed his belief that in this method of examination there lay a great future for the detection of flaws in metals and other materials, such as wood and ferro-concrete, upon which the safety of human life often depended. Hitherto the method had been limited, so far as metals were concerned, in that it could be applied only to thin sections. Recently 4 in. of steel had been examined, and he believed that apparatus now in use would be able to penetrate iron and steel up to 9 in. in thickness.

Several interesting papers were presented dealing with the principles, apparatus and technique of radio metallography. Types of X-ray bulbs and tubes were discussed. The behavior of photographic plates to X-rays and the methods of obtaining contrast in photographs through metals were the subjects of two papers.

The practical application of the method relating to the examination of metals was presented in a paper by E. Schneider describing "Researches Into the Industrial X-Ray Examination of Metals at the Laboratories at Le Creusot Works." This paper summarizes: (a) Researches into segregation and blowholes; (b) ex-

amination of tungsten steels; (c) examination of compound metals; (d) location of blowholes, in order to avoid them in working.

Capt. R. Knox, M.D., and Major G. W. C. Kaye, M.A., presented a paper on "The Examination of Aircraft Timber by X-Ray." No difficulty was experienced in detecting concealed knots, resin pockets and grub-holes. Excess or deficiency of glue in glued joints is also readily revealed. Workmanship and material in the interior of completed laminated or box spans and struts have every detail shown up by the X-ray. The center veneers of plywood can be examined by the same means. In most instances the fluorescent screen suffices for this kind of work.

The X-ray examination of alloy steels and the non-ferrous alloys and metals was suggested as an adjunct to the usual metallographical methods. Prof. W. H. Bragg thought it probable that by means of the diffraction effects of X-rays caused by the atoms of a crystal we should be able to examine the nature and extent of the crystallization of substances and thus gain much information to supplement that given by other methods. He also brought out the fact that generally speaking the transparency of a substance is greater the smaller the atomic weight.

American Dye Industry

THE present status of the American dye industry, both as to results obtained in spite of war-time difficulties and as to limitations in competitive ability, is clearly shown in a report submitted to the Committee on Ways and Means by the United States Tariff Commission. The report supplements and brings up to date the Census of Dyes and Coal-Tar Chemicals for 1917.

The production of intermediates has developed to such an extent that the industry is practically independent of imported raw materials; 354,808,315 lb., valued at \$123,817,966, was produced during 1918.

The grand total of all finished products derived from coal tar (exclusive of explosives and poison gases) was 75,494,113 lb., valued at \$83,095,404, reported by 162 firms. The total production of dye during 1918, reported by 77 firms, was 57,155,600 lb., valued at \$61,306,040. This output in 1918 represents a gain of 24 per cent over 1917. Of even greater importance than the gain in output is the fact that over 300 dyes of improved quality were made during the year, over 100 of which represented varieties new to the American industry. In many cases prices of dyes were considerably reduced.

Synthetic indigo was manufactured by only one firm in 1917, the output being 276,000 lb. During 1918 two other firms entered the field, production increased to 3,083,888 lb., and it is stated that the present plant capacity is substantially greater than the pre-war importation, which, in 1913-14, was 8,507,359 lb. Over 12,000,000 lb. of sulphur black was made, as compared with 5,616,458 lb. imported during the fiscal year 1913-14. The corresponding figures for methyl violet, a triphenylmethane dye, are 632,196 lb. and 255,063 lb., respectively. Four azo dyes were produced in excess of one million pounds each; Alizarin yellow G, 2,233,208 lb.; scarlet 2R, 1,188,798 lb.; naphthylamine black 10B, 1,154,682 lb.; benzo blue 2B, 1,523,985 lb. Excellent progress is also reported in the preparation of coal-tar medicinals and photographic materials. It is

interesting to note that the reported production of the highly-prized photographic developer metol (methyl-p-aminophenol sulphate) is 10,975 lb., which is 393 lb. in excess of the 1913-14 importation.

In spite of the rapid advance made by the industry, much remains to be accomplished before German competition can be met. The great group of dyestuffs derived from anthracene, which includes the fastest dyes known, is practically undeveloped in this country. During 1918 only 119,774 lb. of anthraquinone and related colors was produced, while 3,300,000 lb. was imported in 1913-14. However, much experimental work has been done on these dyes and, provided that Germany is prevented from dumping her reserve stocks on the American market, we may expect a substantial increase in production and variety. It will be necessary to improve the methods used for recovering anthracene, so that the residual pitch may still be marketable as a road surfacing material.

DYES AND WAR MATERIALS

As an instance of the close relationships existing between certain dyestuffs and war materials, the manufacture of sulphur black and picric acid is cited. The nitration of monochlorobenzol yields dinitrochlorobenzol, which may be converted into the sodium salt of dinitrophenol by boiling with alkali. This product gives sulphur black by treatment with sodium sulphide and sulphur, or, upon further nitration, picric acid which, in combination with calcium hypochlorite, forms chlorpicrin. It is obvious that a plant making sulphur black in peace times can quickly turn out picric acid and chlorpicrin in a war emergency. In addition, picric acid could be made from the phenol (produced synthetically from benzol or recovered during the fractional distillation of coal tar), used in peace times for the manufacture of germicides, medicinals, dyes, phenolic resins, synthetic tanning materials, etc. Normal consumption of phenol is estimated at 10,000,000 lb. per year, while the output for 1918 was 106,794,277 lb.

LICENSING SYSTEM PROPOSED

In order to determine the best method for protecting the dye industry during the final stages of its development, hearings were held before the Ways and Means Committee during the week of June 16. Joseph H. Choate, Jr., counsel for the Chemical Foundation and the American Dyes Institute, presented a brief showing the need for insuring a permanent domestic industry and outlining the proposed licensing system, which is not in the nature of an embargo, but is a temporary measure designed to admit those dyes which the Licensing Commission finds are unobtainable at reasonable prices from domestic sources. The Longworth bill for import duties on coal-tar products was accordingly rewritten to include a license system which will operate for five years to bar out all dyes and intermediates except as the American industry may need them. The Dye Licensing Commission is to consist of eleven members appointed by the President, five of whom will represent the manufacturers (three of these must be actually engaged in the manufacture of coal-tar dyes) and five the consumers (three of these must be actually engaged in the manufacture of cotton, woolen and silk goods, respectively). The remaining member, who will be the chairman, must not be connected with the dye industry, either as manufacturer or consumer.

Fall Meeting of the American Electrochemical Society

The tentative program for the Chicago meeting of the American Electrochemical Society, Sept. 23-25, 1919, has been announced by the board of directors. Several sessions will be held jointly with the American Institute of Mining and Metallurgical Engineers, which meets in Chicago during the week of Sept. 22.

On Tuesday, Sept. 23, the Society and Institute will go by boat to Gary, Ind., for inspection of the plant of the United States Steel Corp. A symposium on electric steel will be held on the boat and continued at the Congress Hotel in the evening.

Wednesday morning the Society will hold a general session and in the afternoon a joint session with the A. I. M. E. in a symposium on non-ferrous electro-metallurgy. In the evening a special visit will be made to the electric furnace display at the National Exposition of Chemical Industries at the Coliseum.

Thursday will be devoted to a symposium on catalysis, to be followed by a smoker in the evening.

On Friday the Institute may hold its symposium on pyrometry, to which members of the Society are invited.

Headquarters of both the Society and the Institute will be at the Congress Hotel, and according to present plans all sessions will be held there.

The American Electrochemical Society's headquarters at the Chemical Exposition will be Booth 229, on the balcony of the Coliseum.

House Passes Water-Power Bill

The House of Representatives has passed the water-power bill in spite of the fact that it had become entangled in such a way as to jeopardize early action on it. The bill is substantially the same as the Administration measure which the House of Representatives passed at the last session of Congress and which the Senate failed to consider in the closing days of its session. The measure provides for the granting of fifty-year licenses to construct and operate hydro-electric projects in the United States. The Federal Water Power Commission, which is the licensing body, is composed of the Secretaries of Interior, War and Agriculture. Provision is made for the recapture of projects at the end of fifty years and for the regulation of rates.

The measure is now before the Commerce Committee of the Senate and will be taken up by a sub-committee of that body shortly after Aug. 1, when Senator Jones of Washington, chairman of the committee, is expected to return from a visit to Seattle. The other members of the sub-committees who will have jurisdiction over the bill for the time being are Senators Nelson, Lenroot, Bankhead and Fletcher. Friends of water-power legislation in Washington predict the early passage of the bill by the Senate, but in legislative circles at the Capitol it is well understood that the question of foreign affairs relating to the Peace Treaty and League of Nations will have an important effect upon the early passage of any legislation.

During the short debate in the House preceding the passage of the bill, attention was called to the fact that Congressional delay in providing for water-power development has been in large measure responsible for the power shortage that we experienced during the war, and that further delay should not be tolerated.

Notes and Data on Fixed Nitrogen Plants

COST figures at the Government's cyanamide process nitrate plant at Muscle Shoals were made public for the first time during the recent hearings before the Committee on Military Affairs of the House of Representatives. Tabulations were presented showing the detailed costs of manufacturing calcium cyanamide and ammonia gas, nitric acid and ammonium nitrate therefrom this spring when the plant was operated at 20 per cent of its capacity in a test run. An estimate is given also of the costs had the plant been operated at full capacity. No charges are made on such important accounts as interest on the thirty-odd million dollars capital invested or plant depreciation and obsolescence, taxes and insurance. Undoubtedly a very large percentage of the investment in the plant should be

written off against war expenditures, as it was constructed at extraordinarily high cost to protect our army against any possibility of defeat due to nitrate supplies from Chile being insufficient or our inability to expand the by-product coal industry so as to obtain sufficient amounts of ammonia. General Williams, Chief of Ordnance, in reporting on nitrate reserve stocks estimated that 24 divisions (1,400,000 men) will use 400,000 tons of sodium nitrate per year. At the time of the signing of the armistice, Col. Burns reported that the Government possessed a stock of 700,000 tons of nitrate and an equivalent of 200,000 tons in finished explosives; 400,000 tons was turned over for agricultural use, leaving an equivalent of half a million tons for military reserve. This, in comparison with our 44,000-ton stock of nitrate at the beginning of the war, gives a good military index number.

In reply to Mr. Quin's question as to converting the

MANUFACTURING COST OF GRAINED AMMONIUM NITRATE AT U. S. NITRATE PLANT NO. 2

When hydro-electric power from Muscle Shoals dam is developed we should be able to obtain power, under the same assumption as governing this table, at a maximum cost of \$0.001 per kilowatt-hour. On this basis the cost of "cyanamide fertilizer" would be reduced from \$40.77 per ton to \$31.09.

nitrate plants over to the production of commercial fertilizer, Col. Burns said:

I think that is a problem in itself, Mr. Quin. I doubt if anybody could give you a definite answer. I know that we hope to utilize the plants for manufacturing commercial fertilizer, but there are one or two problems that will have to be solved before one can defi-

nately say that the scheme is feasible. In the first place, money has to be appropriated by Congress for the operation of the plants and we will undoubtedly have to prove to you that we have a commercial product. We know that we can produce cyanamide, which is an absolutely satisfactory material for war purposes, for the manufacturing of ammonium nitrate and other explosives, but cyanamide at present is not admitted to be a thoroughly satisfactory fertilizer.

I doubt not that small amounts are satisfactory. When you mix cyanamide with the ordinary mixed fertilizers in very small quantities you get no toxic effects therefrom, but if you increase the percentage very materially you may get toxic effects. That is the subject of one of our lines of experimentation at the present time.

An agricultural research is now being made and it is expected that the present difficulties will eventually be overcome.

Plants Nos. 3 and 4 at Toledo and Anchor, Ohio, are to be salvaged. Six million dollars has been spent on each of them and they are only 20 per cent completed. Twelve million dollars has been used in the construction of No. 1, but certain process troubles have prevented operation. A commission has been sent to Germany to study the Haber process, a modification of which was to be used.

Blast-Roasting and Its Effect on Blast-Furnace Design

By WALTER K. MALLETT

Item	Estimated Manufacturing Cost per Ton at No. 2	Market Price per Ton	Units of Ammonia per Ton	Price per Unit of Ammonia
Cyanamide:				
Estimated manufacturing expense per present contract prior to June 1, 1921	\$40 03		24	\$1 67
Estimated manufacturing expense per present contract after June 1, 1921	40 77		24	1 70
Estimated manufacturing expense per present contract after June 1, 1921, assuming hydro-electric power from Muscle Shoals dam available	31 09		24	1 30
Ammonia gas:

Sodium nitrate, at present		81 50	19	4 26
Sodium nitrate, normally		45 00	19	2 37

MODERN blast-roasting has resulted in great improvement in metallurgical practice at smelters throughout this country, and this has led to changes in design of various parts of the plant. This is more noticeable in the design of the modern blast-furnace than in any other part of the works.

Sintering of fine sulphides and the agglomeration of other fine material in this sintered product has resulted in a much coarser and more open charge in the furnace. This coarse charge offers less obstruction to the passage of the blast and has greatly increased the tonnage output of the blast-furnace. This improvement is much more noticeable in lead furnace practice than it is in the copper plants, where reverberatories have largely supplanted blast-furnaces.

A few years ago, blast-furnaces were invariably de-

signed with a short, abrupt bosh directly above the tuyeres. This bosh was ultimately eliminated from the end jackets and the ends of the furnace made straight. The necessity for a bosh of this type has been largely eliminated by blast-roasting of ores and the resultant coarsening of the furnace charge, as it is no longer necessary to support the charge at a point above the tuyere line in order to permit the blast to penetrate to the center of the furnace.

A modern lead blast-furnace, where sintering eliminates the fine material from the charge, should be designed with a gentle, continuous bosh from crucible to the top of the jackets and with perpendicular ends. The slope, or bosh, will depend upon the reduction in volume of the descending charge, the rate of descent being kept uniform from the top of the furnace to the tuyere line. The Bunker Hill furnaces are of this type and operate very satisfactorily.

The day of the brick top, supported on mantel beams, has passed, and modern practice is to use two tiers of water jackets surmounted by cast iron or cast steel plates. This provides a furnace unusually free from incrustation and eliminates the necessity for cutting the blast and barring down accretions. It also gives less obstruction on the furnace floor and, consequently, better working conditions.

The greater porosity of the furnace charge makes it desirable to increase the height of charge column so that, in place of the 15 or 16 feet which has usually been considered the best working height, 22 to 24 feet may now be carried with far greater success. This necessitates greater blast pressure and allows a slight increase in furnace width, so that an up-to-date lead furnace should have a width of about 50 inches, a charge column height of about 22 feet and use a blast pressure of about 60 ounces.

Such a furnace will operate with very little trouble. The higher blast-pressure will give a zone of intense action near the tuyere line and the furnace will be free from blow-holes. The elimination of hot tops reduces the dust losses and the high blast-pressure enables the furnace to handle variations in charge with great ease.

COMPROMISE WITH AUSTRALIAN PRACTICE

Riddell has pointed out some of the advantages observed by him in Australia on furnaces of this type, although the Australian practice goes to limits which are hardly applicable to the majority of ores in this country. It is rare that we would encounter conditions which would warrant a furnace 56 in. in width with a 27-ft. ore column. However, we can compromise between this extreme and our previous practice to material advantage.

The thimble top, adopted in some instances, seems to offer advantages, although it is doubtful whether this can be universally applied. At the Selby plant this method of drawing off the gases presents distinct advantages as hand feeding is still in use. The thimble, with stack or downtake protruding through the feed floor, adds complications to mechanical feeding, but it is quite possible that the thimble could be designed with the downtake below the feed floor, leaving the latter clear for the operation of charge cars. A downtake on each end of the furnace, connected to the thimble, would give the best results.

It seems quite likely that Arthur Dwight's idea, to which he gave expression some years ago, of feeding the furnace by means of belt conveyors will be prac-

tically applied in connection with the use of the thimble top. It is certainly feasible and would undoubtedly result in a considerable saving of labor.

Increased tonnages of output of the lead blast-furnace will lead, ultimately, to a trapped spout and a continuous slag flow.* This has not been attained as yet, but the period between taps has been so reduced, in some instances, as to bring this condition within reach.

Double roasting has eliminated the matte problem so that it is quite possible to operate a lead blast-furnace without matte fall. However, this is of doubtful value, as the presence of a certain amount of matte in the furnace keeps it in better condition and is worth the cost of retreatment in the improved furnace conditions. Keeping the matte fall to 2 per cent gives excellent results in the majority of cases, and this amount of matte is a valuable material with which to regulate the condition of the roast. A judicious use of matte will assure a good hard roast under almost any conditions, and in order to operate the blast furnace with the greatest success, the physical as well as the metallurgical conditions of the roast must be closely watched.

REDUCTION OF MATTE FALL IN LEAD SMELTING

The reduction in matte fall has eliminated the great need for double settling, and the smelting of slag shells is also being gradually discarded, although there are still quite a number of metallurgists who maintain that a furnace cannot be successfully run without a bit of slag. With reduced matte fall and reasonable settling, the value of the slag shells is not much greater than in the discarded molten material and this will rarely pay the cost of rehandling and retreatment. It is more profitable to discard the shells and replace them with ores in which there is a margin of profit.

In the copper plants, the reverberatory still holds the front rank, but it seems likely that much of the work which is now done in the reverberatory furnace could be performed just as successfully in the blast-furnace in conjunction with blast roasting. There has been less change in the design of copper blast-furnaces than in the case with lead furnaces; blast-roasting cannot be said to have affected the design of copper blast-furnaces to any appreciable extent. The long Mathewson type of furnace is still in favor and continues to perform satisfactorily. Crucible plates have been lowered and are now set on I-beams resting on the foundations. Brick tops were eliminated a number of years ago and long, narrow jackets are very generally used.

The future may bring out improvements in copper blast-furnace design and practice which will make it once more a rival of the reverberatory, but it cannot be said to have been very greatly improved during the past five or six years.

601 Wells-Fargo Building,
San Francisco, Calif.

Mineral Acid Production.—Mr. A. W. Hawkes, vice-president of the General Chemical Co., recently stated that at the close of the war the company was producing mineral acids at a rate of 420,000 tons annually. This is about two-thirds that of all the plants in the British Isles. The total production of the United States grew during the war from 3½ to 7½ million tons of 50 deg. B., with plants under way for nine.

*Editor's Note—"Mathewson" top was in use in Pueblo for many years.

Electrolytic Caustic Soda-Chlorine Cells

Review of the Patent Situation—Four Classes of Cells Defined: Diaphragm, Mercury, Bell and Fused Electrolyte—Chart: Product Proportions, Current and Energy Efficiency, Kilowatt Consumption and Current Cost Per Unit of Products

BY KARL HORNE

THE basic patent¹ on caustic chlorine cells was granted to Charles Watt long before the era of dynamo generators and cheap electricity. Watt obtained his current from Daniel cells in series. Nevertheless prices were correspondingly high, for the chemical caustic soda and chlorine market still had fifteen non-competitive years ahead of it before Messrs. Solvay, Weldon, Deacon et al. were to initiate "The War of the Alkali Industry." Watt was an able chemist, as will be appreciated upon examining his patent description, which anticipates the actual development this process has taken, namely: Diaphragm cells for the production of pure chlorine and alkali; fused electrolyte, metallic sodium, etc.; and mixed electrolyte, hypochlorites and chlorates.

Approximately three hundred inventors have received patents subsequent to Watt's invention. Billiter's² and Lucion's³ Abstracts describe most of these. The former gives a digest of the patents on the diaphragm and bell type of cell on which there were 256 British, 136 German and 127 American patents granted previously to 1911. The American patents are in group 204—Electrochemistry, subdivisions 1, Aqueous Bath; 4, Anodes; 5, Apparatus; 6, Cathodes; 28, Diaphragms, and 58, Alkali and Chlorine. Less than twenty issues have been made since 1911 and a complete set of copies can be obtained from the Patent Office for about \$7.

In conception the electrolytic method of making caustic soda and chlorine from brine is extremely simple. The requirements are merely a pair of electrodes and the passage of direct electric current from one to the other in the brine. The primary products formed in so simple a cell, however, would immediately enter into secondary reactions and not be available as desired. The numerous modifications of the simple cell that have been brought out represent just so many attempts to eliminate or control these secondary reactions. The merits of the several electrolytic processes will be better understood after reviewing the underlying facts of alkali chloride electrolysis.

AMPERE-HOUR EFFICIENCY

When a current of electricity is passed through a solution of common salt, positively charged sodium ions pass to the cathode (negative electrode) and negatively charged chlorine ions pass to the anode (positive electrode). The chlorine ions give up their negative charges on contact with the anode and are liberated as free chlorine gas or remain dissolved in the liquid surrounding the electrode. At the cathode the sodium ions give up their positive charges and immediately

react with the water of the electrolyte, liberating hydrogen and forming caustic soda. Thus the products of electrolysis are chlorine, caustic soda and hydrogen, all of which are valuable commercially. Unless prevented by the construction and operation of the cell the following secondary reactions are presumed to occur in some degree: The hydroxyl ions formed at the cathode will carry negative charges to the anode exactly as the chlorine ions do. These hydroxyl ions, however, have almost three times faster migration velocity than have the chlorine ions and consequently carry, in proportion to their concentration, a larger part of the current. Arriving at the anode, the OH ions are discharged, with the result that oxygen is set free, together with the chlorine. The sodium hydroxide, which must be in equilibrium with the OH ion passing through the anolyte, reacts with the dissolved chlorine, forming hypochlorite, chlorates and sodium perchlorate in solution, a portion of which are reduced by the carbon anodes forming carbon dioxide in the chlorine gas. The chlorine dissolved in the anolyte may also come in contact with caustic by diffusion with the catholyte and bring about the same secondary reactions.

The aim of the various processes is to remove the products, chlorine, caustic and hydrogen, from the zones of electrochemical activity as rapidly as they are formed and so to avoid the secondary reactions. If this were accomplished, no current would be used in secondary reactions, and the current efficiency would be 100 per cent; that is, each ampere-hour would produce 1.3220 g. of chlorine, 1.4910 g. of sodium hydroxide and 0.03750 g. of hydrogen. Ampere-hour efficiencies obtained in practice vary from 90 to 98 per cent.

ENERGY EFFICIENCY

The energy efficiency depends not only upon the current efficiency but also upon the cell voltage. The cell voltage may be considered as made up of two parts—the voltage of decomposition of the solution and that required to overcome the resistance of the solution and of the electrodes. The decomposition voltage of brine is approximately 2.3, and until the applied pressure exceeds this critical value no current is forced through the cell. Cells operate usually at from 3 to 7 volts, depending upon design, temperature and current density. If a cell had 100 per cent current efficiency and could operate at a pressure of 2.3 volts, its energy efficiency would then be 100 per cent. In practice energy efficiencies range between 30 and 75 per cent. The difference in voltage of different cells depends almost entirely on the current density and length of current path in the electrolyte. This is evident from the fact that the resistivity of 25 per cent or nearly saturated brine is 1.76 ohm-inch, or 24 million times that of pure copper. Consequently a great area of electrolyte and a short

current path are needed to avoid excessive voltage drop. In connection with the operation of plants for the production of chlorine and caustic soda electrolytically, it is desirable frequently to correlate various factors bearing on the cost of production. Repeated application of efficiency formulae, calculations of kilowatt-hours per lb. of chlorine, etc., become irksome even when carried out on a well-oiled slide rule. As a short-cut the author has evolved the chart of co-ordinated curves shown herewith. The continued building of chlorine and caustic soda cells suggests that such a chart may be useful to others. It might readily be used by a plant operator or superintendent having no knowledge of the theoretical considerations on which it is based.

The use of the chart requires little explanation in addition to the example given. The operating current and cell voltage are read from indicating meters usually mounted on the power board. The number of pounds of caustic soda per hour is computed from the weight and concentration of caustic liquor.

FOUR CLASSES OF CELLS

Electrolytic chlorine cells comprise four processes, namely, the diaphragm, the mercury, the bell, the fused electrolyte.

The Diaphragm Process. In this process a porous partition, usually a molded asbestos compound, separates the anode and cathode compartments. All types of diaphragm cells employ the same means of preventing the hydroxyl ions from passing to the anodic space, that is, the flow of the electrolyte itself is made to oppose their passage. The gases, chlorine and hydrogen, accumulate above the surface of the electrolyte and are readily drawn off. The sodium hydroxide is removed from the cathode in part by the flowing salt solution and in part by gravity. Whether it collects at the top of the cathode compartment, as in Le Sueur's cell, or at the bottom, as in the Griesheim, Townsend, Jewell and others, depends upon the relative concentration of brine and caustic where a mixture of these solutions constitutes the catholyte. Thus the specific gravity of a 26.4 per cent or saturated salt solution at 15 deg. C. is 1.2, and the caustic soda will float on the brine unless its gravity is equal to or greater than 1.2, that is, unless its concentration is above 17.7 per cent. A number of diaphragm cells, however, use oil, steam or even air in the cathode chamber.

The earliest commercially successful cell of the diaphragm type was the Griesheim, which was first operated in Germany in 1890. An iron box serves both as container and cathode. The anodes are plates of magnetic iron oxide. The diaphragms forming the walls of the boxlike anode compartments are a composition of cement, salt and hydrochloric acid. In use, the salt dissolves and leaves an extremely fine pored wall. It is essential in all diaphragm cells that this porous diaphragm allow electric current to pass through freely, but at the same time keep the caustic alkali of the cathode compartment from mixing with the saturated salt solution of the anode compartment. In the Griesheim cell the accumulation of the sodium hydroxide causes the waste of current from secondary reactions to increase and when about one-third of the sodium chloride has been decomposed it is necessary to shut down and draw off the caustic. Griesheim cells are steam-jacketed and the electrolyte temperature is maintained between 80 and 90 deg. C. The anode cur-

rent density is from 10 to 20 amperes per square foot. Other diaphragm cells in operation are the Hargreaves-Bird, in Middlewich, England; the Townsend, at Niagara Falls; Le Sueur's, at Rumford Falls, Maine; the Outhenin-Chalandre, used extensively in France, Switzerland, Italy and Spain; the Billiter-Siemens, at Niagara Falls and in Europe; the Billiter-Leykam, in Austria; the Finlay, operating in Belfast; the Allen-Moore, at Portland and Philadelphia; the Nelson, in West Virginia; the Wheeler, in Wisconsin, and the Jewell, in Chicago.

The Mercury Process. The mercury process uses anodes of carbon and a cathode of mercury. The sodium liberated by electrolysis amalgamates with the mercury and the amalgam is transferred mechanically to an adjacent compartment containing water. The amalgam is decomposed by the water, resulting in the formation of sodium hydroxide with the evolution of hydrogen and freeing of the mercury, which is returned to the electrolyzing chamber. Chlorine is collected above the anodes. NaOH so formed is very pure.

The Castner and Kellner cell in England was an early representative of this type. While the efficiencies are good, the initial cost is extremely high. A plant having a capacity of one ton of chlorine per day would contain about 13,000 lb. of mercury. Other mercury cells are the Solvay-Kellner, the Rhodin and the Wildermann.

The Bell Process. The bell type, of which the Aussig is the original, uses neither diaphragm nor mercury, but depends upon gravity for partial separation of the caustic soda and salt solutions. The chloride drawn off with the dilute caustic crystallizes out in the process of concentration of the caustic by evaporation. The Aussig comprises a bell of non-conducting material supported in an open tank. A carbon plate suspended horizontally inside the bell serves as anode and a sheet iron coating upon the outer surface of the bell constitutes the cathode. Brine is fed into the anode compartment. The current passes from the anode down under the edge of the bell and up to the cathode. Chlorine is drawn off through an opening in the top of the bell, while the heavy caustic formed at the cathode sinks and is drawn off at the bottom of the container. In practice a single tank contains twenty-five bells operating in parallel. The bell cells are free from diaphragm troubles, reliable in operation and low in initial and maintenance cost.

The Jewell bell-type cell is a modification of the older bell types. Stratification in its cathode compartment is aided by the addition of water and dilute caustic rises as formed. The Jewell claims ability to use impure brine, high current efficiency at high current densities and low cost for attendance and upkeep. The Jenkins is also a modified bell type of cell.

The Fused Electrolyte Process. This is also known as Acker's process and was at one time operated at Niagara Falls. The graphite pins which serve as anodes dip into a bath of fused salt. The salt floats on a cathode of lead maintained molten by the current it carries. The action is similar to that of the mercury process. The electrolyzed sodium forms an alloy with the lead, is removed from the cell and decomposed by steam to form sodium hydroxide and hydrogen. A current density of about 20 amp. per sq.in. of lead keeps the bath in a molten state. The concentration of caustic produced averages 94 per cent. The concentration of chlorine is 10 per cent, an extremely low figure. The energy efficiency is also very low.

ELECTROLYTIC CAUSTIC SODA-CHLORINE CELL CHART

Typical Solution of a Problem:

Given:

Operating current, *A*.....840 Amp.
 Operating pressure per cell, *D*.....4.15 V.
 NaOH produced per hour, *B*.....2.5 lb.
 Kw-hr. rate0.8 c.

Readings:

Lb. chlorine per hour, opposite 2.5 read.....2.42
 Theoretical lb. of salt per hour, opposite 2.5 read.....3.66

Cu.ft. hydrogen per hour, opposite 2.5 read.....11.4
 Amp-hr. efficiency, line *C* at intersection *A* and *B*, at
 end90%
 Energy efficiency, line *E* at intersection *D* with amp-hr.
 efficiency, at end50%
 Kw-hr. per lb. chlorine, on cross-scale, linear slide, read 1.58
 Energy cost, align 1.58 and 0.8 on logarithmic scale
 read1.26c.

On the basis of efficiencies shown in published reports, an enterprise contemplating the manufacture of chlorine would select the Finlay cell. The selection of the type of cell, however, and the installation of a plant happen to require many other considerations such as initial cost, attendance charges, upkeep, floor space, overload capacity, cost of energy, continuous or off-peak operation, market for products, etc. While it is not to be expected that complete and reliable data on these various features can be available in so new an industry, there are a number of outstanding characteristics of processes and of individual cells that bear on the above named factors.

While diaphragm renewal is necessary in cells of the diaphragm type, it is looked upon rather as a matter of cell upkeep than as operating trouble. Where the brine is properly pretreated the cells are operated from six to twelve weeks or even longer without serious falling off in efficiency or output. The mechanical cleaning of diaphragms in operation has been suggested, but the nature of the stoppage would seem to make this impracticable, if not impossible. Chemical cleansing of the cell pores is also unpromising on account of the activity of the chlorine on one side and of the caustic on the other. The diaphragm type cells are the most satisfactory on the market at present.

Offsetting the many advantages of the mercury cell are the comparatively large investment and large floor space required and the difficulty of removing impurities from the mercury. The high fixed charges can be compensated only by low energy costs, mercury cells being thus limited to regions of abundant water power.

The bell type require comparatively large floor space. Their low energy efficiency is offset by low investment, upkeep, and attendance charges. The possibilities of increasing the energy efficiency by decreasing the operating voltage offers a promising field for experimenters. The voltage above the brine decomposition voltage (2.3) is used entirely in overcoming the internal resistance of the cell. Since the resistivity of the electrolyte is about 400,000 times that of hard cast iron and 5600 times that of carbon, it is evident that, as pointed out above, by far the greater part of the voltage drop in a bell cell is due to electrolyte resistance and a very small part to electrode resistance. The problem, therefore, is to increase the area and decrease the length of the path of the current in the electrolyte and at the same time provide for the removal of the products of electrolysis without the undesirable secondary reactions. Because the area of the electrodes usually varies with the area of current path through the electrolyte and therefore with the voltage, undue importance seems to have been attached to electrode area and electrode-electrolyte contact resistance. Experience has shown that density of current in the electrolyte is the factor of prime importance. If the electrolyte current density factor is taken care of at all points, there will be no question of electrode-electrolyte contact resistance.

The capacity of rating of a cell should be based on the output of products of standard purity with maximum energy efficiency. The overload capacity would then be defined as the maximum rate of production which gives such standard products regardless of energy efficiency. Capacity stated in pounds or kilos of chlorine per 24 hours is definite; expressions such as "a 2000-ampere cell," sometimes used, are without meaning in stating capacities.

The value of overload capacity in the economics of production depends upon the relation among a number of factors. It is evident that to increase the output increase of the current density is required, and to increase the current density higher voltage, resulting in lower energy efficiency and higher energy cost of production, is required, but the higher rate tends to decrease the cost of production by cutting down the fixed charges. It follows that there is a point of maximum economy readily determinable in any given case. Thus it was found that a certain plant operating with highest ampere-hour efficiency at two tons of chlorine a day could be operated most economically at four tons a day.

The character of load afforded the central station by electrolytic chlorine plants is most attractive. The low voltage energy of unvarying amperage may, for many types of cell, be taken directly from a rotary converter at the available pressure, say 110 to 500 volts. For example, a type of cell using 1500 amperes at 3.5 volts could be connected 30 in series on 110 volts, in which case the required converter capacity would be 165 kw. Such a plant would produce, say, 2880 lb. of chlorine per 24 hr. Voltage regulation is unnecessary. In addition to these attractive features, such a plant, if equipped with the proper type of cell, permits of off-peak operation.

The increasing demand for chlorine, its numerous products and its by-products must lead to the development of a recognized standard type of cell comparable in efficiency, durability and ease of operation with other standard electrical apparatus. This ultimate type of cell will doubtless have an energy efficiency above 80 per cent; it will operate with little attention, and its elements will require renewing infrequently as do those of a storage battery. Ordinary impurities in the salt and water will have no effect on its efficiency and will be periodically removed as simply as a boiler is blown off.

Many cells now in use cannot be shut down without taking special precautions to prevent mixture of brine and caustic, destruction of anodes, or other bad effects. The ultimate type will be unaffected by interruption of energy supply.

With the development of the efficient and dependable cell for the production of chlorine will come the development of simpler and safer methods for its utilization. Which of the fields of its present application will come to demand the bulk of the output it is impossible to foresee. Most interesting to the chlorine manufacturer, to the central station power salesman and to the industrial engineer is the fact that wonderful growth in the electrolytic chlorine industry appears to lie immediately ahead.

Civil Service Examinations

Metallurgist (Male).—A vacancy exists in the Navy Yard, Norfolk, Va., at \$2800 a year. Bachelor's degree in metallurgy or mining engineering and at least three years' experience in metallurgy, including inspecting and testing of metals, are required. Applications must be filed prior to July 29, 1919.

Metallographist (Male).—A vacancy exists at the Engineering Experiment Station, Naval Academy, Annapolis, Md., at \$7.52 per diem. Applicant must have bachelor's degree in chemistry, engineering or metallurgy and must have had not less than one year's experience in the use of the microscope in the examination of metals. Examination closes July 29, 1919.

The Langmuir Postulates

An Introduction to Dr. Irving Langmuir's Theory of Chemical Reactions, Showing the Method of Determining the Physical Qualities of Chemical Compounds From Their Atomic, Ionic and Molecular Structure—A New Theory of the Constitution of Atoms and Molecules

BY ELLWOOD HENDRICK

I

THE address of Dr. Irving Langmuir delivered at the Buffalo meeting of the American Chemical Society on "The Arrangement of Electrons in Atoms and Molecules" made such a deep impression upon those who heard it, and the potentialities of the Langmuir postulates loom so large as applied to research, that we resolved to give our readers a report on the subject as soon as this could be made ready. The first original paper appeared in the June number of the *Journal of the American Chemical Society*. Owing to the intense concentration of the text it is not easy reading, even to the average chemist, and in what follows we shall not attempt to cover the field with thoroughness, or even to touch upon problems that require experience in applying the postulates. Our purpose is to write an introductory chapter, and to begin "further back" for the benefit of those who have not followed diligently the voluminous literature of research on the structure of atoms and molecules. We shall not even attempt to make the line clear between the Langmuir postulates and the work of other men in research whose conclusions are in part accepted. We are dealing with a new philosophy of chemistry which differs from that of the present text-books in various concepts, but which provides a definite means of determining upon the arrangement of atoms in combination, as well as that of electrons in atoms and molecules.

PRACTICAL VALUE OF THE THEORY

We shall try to give at least a glimpse of its amazing practicality when applied in the laboratory. It is, in effect, a new angle of attack which calls for new mental processes; and, as with any new tool, these seem difficult at first. When we state, however, that with adequate understanding and experience, it becomes possible to predicate the physical and chemical qualities of a substance, even to its crystalline structure, before it is synthesized; that it opens up a new and workable theory of valence; that it explains the curious manifestations of the elements of the rare earths and other elements in the periodic table, the irregularities of nitrogen, and the magnetic properties of the iron and platinum groups of metals, as but a part of its contributions, we need give no further emphasis to its value as an aid to technology as well as to research. We shall not undertake to make all these facts clear. Our purpose is to lure the reader into a consideration of the subject, so that he may approach Dr. Langmuir's present and future papers with that quality of interest which is warranted by their importance.

For lack of space and with a view to confining ourselves to the simplest features in this article we shall omit discussion of the principle involved in the second

dary planes (Postulate I) in connection with the position of electrons in atoms of greater complexity, also the magnetic forces as indicated in Postulate V, and the illumination shed upon the great work of Werner, and refer the reader to the first paper in the June number of the *Journal of the American Chemical Society* for the explanations and a much more comprehensive discussion of the entire subject in a very condensed form.

We are indebted to Dr. Langmuir for a number of extended interviews, and we express our sincere obligations to him for his patience in exposition.

STRUCTURAL RESEMBLANCE OF N_2O AND CO_2

By way of indicating the workings of the theory let us take as an example two gases that we have not heretofore regarded as having any qualities in common: N_2O , or laughing gas, and CO_2 . According to the Langmuir postulates, as we shall try to develop them in part, these gases display a remarkable resemblance in the structure of their molecules, containing each the same balanced number of positive and negative charges, and the same exterior arrangement of electrons, so that, were they magnified to visibility, and the kernels of the atoms hidden from view, we should be unable to tell them apart by looking at them. At least it is a fair guess that by looking at them, under these conditions, we should be unable to distinguish them, one from the other. Then we conclude that they must have certain physical properties in common. The figures which follow have not been published elsewhere at the present writing; we are indebted for them to Dr. Langmuir, who will present them later on with detailed explanation in the *Journal of the American Chemical Society*, but they will serve to indicate the points of remarkable similarity in the physical properties of two gases which Dr. Langmuir concludes to be similar in structure. The records are taken from unrelated pages of published works:

	N_2O	CO_2
Critical pressure, atm. spheres	75	77
Critical temperature, deg. C.	35.4	31.9
Asymmetry at 20 deg. C.	148×10^{-6}	148×10^{-6}
Heat conductivity at 100 deg. C.	0.0506	0.0506
Density of liquid at 20 deg. C.	0.996	1.031
Density of liquid at -10 deg. C.	0.856	0.858
Refractive index of liquid, D line 16 deg. C.	1.103	1.103
Refractive index of gas at 40 atm., 16 deg. C.	1.558	1.582
Dielectric constant of liquid at 0 deg. C.	0.12	0.12
Magnetic susceptibility of gas at 40 atm., 16 deg. C.	1.305	1.780
Solubility in water, 0 deg. C.	3.25	3.13
Solubility in alcohol, 15 deg. C.		

Both gases form hydrates, $N_2O \cdot 6H_2O$ and $CO_2 \cdot 6H_2O$. The vapor pressure of the hydrate of N_2O is 5 atmospheres at 6 deg. C., while the hydrate of CO_2 has this vapor pressure at -9 deg. C. The heats of formation of the two hydrates are given respectively as 14,900, and 15,000 calories per gram-molecule.

The surface tension of liquid N_2O is 2.9 dynes per sq.cm. at 12.2 deg., while CO_2 has this same surface tension at 9.0 deg. C.

Thus N_2O at any given temperature has properties practically identical with those of CO_2 at a temperature of 3 deg. lower.

These results indicate the similarity of the outside structure of the molecules.

DISAGREEMENT IN FREEZING POINT

There is one property, however, that is in marked contrast to those given above: the freezing point of N_2O is -102 deg. C. while that of CO_2 is -56 deg. This may be taken as an indication that the freezing point is a property which is abnormally sensitive to even slight differences in structure. The evidence seems to indicate that CO_2 is slightly more symmetrical and has a slightly weaker external field of force than that of N_2O .

It would be hard to find such an array of coincidences unless there were reasons for them, and it is one of the purposes of this paper to show reasons for them, as we proceed.

All of these figures have been gathered by painstaking research in the past. They were uncorrelated and uninteresting. But in the light of this theory we find them ranging themselves into such subtle correlation as to cause them to function as parts of that greater whole which men of research are ever trying to discover. For decades these figures have been available. But in this case, as in that of other bodies which we shall consider later, the identical physical characteristics of those of like structure have remained unobserved.

II

At the end of the paper we present the postulates upon which the work is based, and we shall refer to them from time to time as we proceed. But, going "further back," as we promised to do, let us consider every atom as made up of two component parts: the electro-positive charges concentrated in the nucleus of each atom, which is individual and peculiar to each element, and the electrons which are electro-negatively charged, and which, from their positions about the nucleus, neutralize the positive charges on it. *The electrons are arranged in a definite configuration about the nucleus of each atom.* They are not of necessity held absolutely still. There is no reason why they may not move about, but the area of activity of each electron that forms a part of an atom is circumscribed within limits of space similar to that of its neighbor. Unlike the nuclei which, as we have just said, are held to be peculiar to each element, we consider the electrons to be all alike.

Now let us bear in mind the atomic numbers of the elements in the order of their atomic weights in the periodic table. They are: H, 1; He, 2; Li, 3; Be, 4; B, 5; C, 6; N, 7; O, 8; F, 9; Ne, 10; Na, 11; Mg, 12; Al, 13; Si, 14; P, 15; S, 16; Cl, 17; Ar, 18; K, 19; Ca, 20; Sc, 21; Ti, 22; V, 23; Cr, 24; Mn, 25; Fe, 26; Co, 27; Ni, 28; Cu, 29; Zn, 30; through to U, 92.

ATOMIC NUMBER COINCIDES WITH ELECTRO-POSITIVE CHARGES

Thanks to the brilliant Moseley of Manchester, England, killed as a private soldier in the flower of his youth in the Gallipoli fight, we have confirmation of the statement that the atomic number of each element in the periodic table and the number of electro-positive charges on the nucleus of its atom are the same. Thus from the above we read that the number of positive

charges on the nucleus of the hydrogen atom is 1; that of the lithium atom is 3; carbon, 6; nitrogen, 7, and so on, so that the table of atomic numbers is also that of the positive charges on the nucleus of the atom of each element. From this we gather also that the nucleus of the atoms of no two elements can be the same, and we learn, too, that the table of atomic numbers gives, in addition to the foregoing, the number of electrons that are attached to, and form part of, every atom of every element. There must be an electron to neutralize every positive charge, because the difference between an atom and an ion is that in the former every positive charge of the nucleus is satisfied with an electron, and is therefore neutral, while in an ion this is not the case. In an ion there are either more or fewer electrons than will completely balance the positive charge of the nucleus of the atom, or the nuclei of the atoms, which constitute it.

In acknowledging and accepting in part certain theories of W. Kossel and G. N. Lewis, Dr. Langmuir carries them further, with various changes and extensions, but, as already stated, for the sake of brevity we shall not attempt to indicate the specific authorship of each idea.

III

By themselves electrons repel each other, but in the presence of positive charges they show a disposition to arrange themselves into definite groups; they indicate a law, or series of laws, of configuration, and this is the first step in the present work. If, then, these groupings, these configurations, may be found complete in the most stable of the elements, and incomplete in others, we may infer that in the inert gases the electrons are satisfied, that they have fulfilled their tendency to conform to certain arrangements, and that the activity of other elements is due to the drive to conform as nearly as possible to the complete, and therefore inert, elements. The author of these postulates will have nothing to do with metaphysics in the development of his theories of the constitution of atoms and molecules, but we cannot resist the observation that in this pair-forming and octet-forming nature of electrons about positive charges we find suggested the tendency in nature toward a condition of balance and rest which is the basis of the great postulate of Gautama Buddha, and the substance of the ancient philosophy of the East.

HELIUM THE MOST STABLE ELEMENT

Different elements do not behave the same; they differ in their nuclei and in their arrangement and number of electrons, but in this striving to become as nearly as possible like the fixed gases we find the key to all chemical phenomena. It behooves us, therefore, first to consider the most stable element, which is helium. The

atomic number of helium being 2, the positive charge of its nucleus is 2, and it has two electrons. How are these arranged? There being but two they cannot follow an isometric system: the simplest would be the tetragonal system, having, like the earth,

FIG. 1

a polar axis and an equatorial plane (Postulate I). We imagine these two electrons as held by the positive charges of the nucleus very much as though the nucleus were in the center and the electrons each in the half of a complete shell, say, like a walnut-shell, that surrounds it. Neither electron crosses the plane which divides these two hemispherical shells. We might picture, as in

Fig. 1, a cross section of the helium atom, cut a little above the equator, so as to show all charges, the positively charged nucleus indicated by ++ and each of the electrons by a — sign.

IV

This must be the most permanent arrangement of electrons about a nucleus: one electron in each half of a spherical shell, and neither trespassing upon the territory of the other. And while there is no reason to regard the electrons as stationary, save that each keeps within what we call its cell, it will be convenient for us to consider each as occupying its average position, which would be on an axis perpendicular to the plane which divides them. Here we have a complete satisfaction of the positive and negative charges with almost no force extending beyond the atom in any direction. Let us say the electrons have achieved a position of complete balance and contentment, thus making helium the most permanent substance known. Because there is practically no external force about the atoms, and the primary disposition of its electrons to form pairs is satisfied, the atoms do not form molecules; they remain independent and inert. So independent and inert are they that not only is He a gas, owing to the lack of external force about its atoms, but these atoms are readily separated, and its boiling point is therefore only $4\frac{1}{2}$ degrees above absolute zero. We have, then, in helium, the achievement of the first electronic ideal: the grouping in pairs about a positive charge. Such a central part we consider to be common to all atoms except that of hydrogen: the nuclei varying from 2 to 92 positive charges, according to the element, and the first pair of electrons invariably next to the nucleus.

V

The next element to helium in point of stability is neon. Its atomic number being 10, we must find an ideal arrangement of its ten electrons. The nucleus has ten positive charges, and the conclusion is that the first pair group themselves about the nucleus, just as in helium, leaving eight positive charges to be satisfied. These eight electrons arrange themselves in a second shell outside that containing the pair, four in either hemisphere of the outer shell, and each in its own cell. A top view would appear as in Fig. 2, with the nucleus and pair hidden under the outer shell. A perspective view would be as in Fig. 3. These eight electrons, four in either hemisphere of the outer shell, we call an octet. This shell is twice the diameter of that including the pair below it, and its surface is four times as great. This is in order to give the same space or room to each cell. There are eight cells, and every cell in the outer shell of neon is occupied. Now since we hold that chemical activity emanates mainly from the outer shell of electrons, there is no occasion for chemical activity in neon. And bearing in mind this greater chemical activity of the outermost shell we shall follow G. N. Lewis in calling all that part of any atom that is within the outer shell, its *kernel*. The second disposition of electrons is to group themselves into octets, and here they have done it. We have a pair, and an octet, all balanced, all filling every available space, and so there is no chemical activity to neon. It is inert; it is a gas; it has a low boiling-point, and it does not form molecules. It is completely satisfied as

FIG. 2

FIG. 3

it is, and next to helium it is the most stable element. The next element in order of stability is argon, atomic number 18. This is just like neon, except that, according to Postulate IV, each cell of the second shell contains 2 electrons, making 2 in the first and 16 in the outer shell. This is also a permanent gas. In krypton, atomic number 36, we have two in the first shell, $8 + 8$ in the second, and have 18 still to dispose of. The third shell will contain 18 electrons; 9 in each hemisphere. One of these 9 electrons will go to the pole, and the remaining 8 will be distributed symmetrically about it. The same thing happens in the other hemisphere. With xenon we have krypton as the kernel (except that the nucleus has 18 more positive charges) and the 18 more electrons are distributed in the same manner in the third shell, making 2 in each cell, and including one more in a cell at each pole. Niton follows as the last, with 32 electrons in the fourth shell, 16 in each hemisphere.

In other words, we assume these inert and stable elements to be made up of successive and consecutive groups of electrons about the nucleus of each, consisting of first the nucleus, next a pair of electrons, and then consecutive octets and double octets with a pair in the polar position whenever there is an odd number of electrons to be provided for in each hemisphere. According to Postulate IV, all inner shells must have their full quota of electrons before the outer shell can contain any, but we note that in the inert elements the outside shells have their full quotas also. *This is the very reason for the stability and inactivity of these elements*; the electrons are ideally placed, they are electrically balanced, there is a minimum field of external force about the outer shells, therefore they all are gases, and have low boiling points.

No element other than the inert gases has its outer shell satisfied, i.e., every cell of its outer shell occupied, and therefore the electrons in the outer shell are always striving to make pairs or octets with some other electrons. *This is the basis of all chemical combination and reaction.* We shall try to make this more evident as we proceed.

VI

When we consider hydrogen, atomic number 1, we have but a single charge and a single electron. We have not even a pair. The lone electron is ever trying to form a pair, and therefore the atoms pair off in molecules. Note, please, in Postulate VI that a stable pair may be held by two hydrogen nuclei. Of course the hydrogen molecule is not as stable as an inert gas, but compared with a single hydrogen atom which has an exceedingly short time factor for its separate existence, the hydrogen molecule is very stable. It has the lowest boiling point of all substances except He, being but 20 deg. absolute. Due to such complete saturation within itself its external force is slight, and it shows slight chemical activity until it is split up into atoms. The old *status nascendi* theory in regard to hydrogen worked well in that it referred really to unpaired hydrogen atoms. If we take from a hydrogen atom its single electron we have left of course the hydrogen ion.

Lithium with its atomic number of 3 has three electrons, of which two form a pair about its nucleus and which constitute the lithium ion, while the third is easily detached, because it tends to form pairs or octets. We read in Postulate VI that the two atomic ker-

nels can very rarely hold a pair of electrons as is the case with the H molecule. The lithium kernel already has its pair, and therefore it cannot get another nucleus into its kernel. The lithium atom with but one electron in its second shell produces a strong electrostatic field which extends into surrounding space. There being no free nuclei about which the single outside electrons can group themselves into pairs or octets, it is electrostatic force which holds the atoms together, a second upon the first, a third upon the second, a fourth upon the third, and so on, *ad infinitum*, so that it appears to build itself into a solid lattice work structure. Therefore it is a solid. It melts and boils with difficulty. Because of the free electrons it is a good metallic conductor, but for lack of enough available electrons to form octets on the outer shell it has no tendency to form molecules either in a solid, liquid or gaseous state.

PROPERTIES OF FLUORINE IN THE LIGHT OF THE THEORY

Fluorine has the atomic number 9, or one less than neon, so that it has a pair about the nucleus and seven in its outer shell, lacking but one electron to make the octet complete. The cumulative effect of its seven outside electrons to form an octet is so great as to give it intense chemical activity. If brought into contact with lithium it takes the electron from it and completes its octet, making the fluorine ion negatively charged, and leaving the lithium ion positive. Let us repeat this to make it clear. Fluorine has nine positive charges on its nucleus, and about it is, first, a pair of electrons, and then seven more in its outer shell. With seven electrons all placed in a shell with eight cells, and all seven trying to form an octet, the effort is likely to be intense. And it is. Nobody ever called fluorine inert! That lone extra electron of lithium in an outer shell (although, of course, the concept of shells and cells is a concept of space only) is pulled over to the vacant space in the fluorine outer shell. That leaves the lithium ion free. But with nine positive charges on the nucleus of fluorine and ten electrons now engaged, the fluorine ion becomes negatively charged because of ten electrons about its nucleus with + charge of 9. So too the lithium ion, which has a triple positive charge on its nucleus and has lost an electron, has now but two instead of three negative charges, which makes the lithium ion positive. The force, however, which holds this ion to the fluorine ion with its octet of electrons is electrostatic; there is no opportunity for pairs of electrons to be held in common by the two elements, therefore there is no LiF molecule. Every lithium ion is attracted to all the negative fluorine ions about it, and *vice versa*, so that it builds up a lattice work of the two ions, as in Bragg's salts. It is a solid, but it is a non-conductor, because there are no free electrons, every octet being satisfied. If, however, we melt it, then it becomes an electrolytic conductor, because the ions are then free to move around.

RELATIVE CHEMICAL ACTIVITY OF HALOGENS

Here is an illuminating note which explains why the halogens decrease in chemical activity as they increase in atomic weight, and therefore in atomic number, while with the alkali metals the opposite is the case. Not only does fluorine stand next to neon, but all the halogens stand next to the inert gases, each having one electron less. Chlorine bears this relation to argon, bromide to krypton, and iodine to xenon. But as these

inert gases increase in atomic number they become less stable, as is indicated by their decreasing ionization potentials and their increasing boiling points. There is greater distance or greater interruption between the positively charged nucleus and the negatively charged electrons in the outer shell as atomic numbers increase. Therefore it stands to reason, among the halogens, that as they increase in atomic number their electro-negative qualities decrease in intensity. On the other hand lithium stands next to helium, and the other alkaline metals bear a similar relation to the inert gases, each having one electron more rather than one less, as with the halogens. This lone electron on the outer shell is given up in the presence of a positive charge; it cannot well draw on seven other electrons to complete the octet. But the electrostatic force between the nucleus and the outermost electron becomes less and less as the kernel grows larger and larger, because the distance between the positively charged nucleus and the outermost electron becomes greater. Therefore the outermost electron becomes more readily detachable as the size of the atom increases, so that sodium is more electro-positive than lithium, while potassium is more electro-positive than sodium.

Carbon, atomic number 6. Here the atom is composed of a pair of electrons about the nucleus, and four in the outer shell. By virtue of the larger charge in the kernel these are not easily given up, as in lithium, but may be regarded as constantly trying to draw on four more electrons to make up an octet. The atom is symmetrical, and its tetravalency is persistent. Its well balanced but incomplete structure explains both its permanency in combination and its high boiling point.

NITROGEN AND ITS COMPOUNDS

Nitrogen, atomic number 7, with 7 electrons, cannot be brought into any symmetrical shape by doubling up its atoms to form N_2 . We have the nucleus with its pair, and then five more electrons in its outer shell, which has room for eight, and the five electrons in the outer shell always trying to form an octet. The only symmetrical form in which we can consider two nitrogen atoms to constitute a molecule is to have them slide together into one, with two nuclei in the centre, each with a pair of electrons, which accounts for four of the 14 electrons in two atoms of nitrogen, leaving ten over. In the outer shell we have eight, and the remaining two may be held imprisoned within the octet. The arrangement (in a tetragonal form) would be as in Fig. 4. We saw a different kind of doubling-up in the hydrogen molecule, and it seems that this assumption for N_2 and a few other gases is a happy one.

Nitrogen forms a series of unusual compounds, some of which are remarkably active and explosive, and its structure indicates a signal departure in properties from the elements that precede it in atomic number. This single octet with a double kernel is not unique with N_2 although it is unusual. It is the only symmetrical arrangement of certain other bodies, and gives rise to some remarkable comparisons; more particularly of N_2 with CO, and also between these and HCN and NO. Let us compare the N molecule with the CO. The N molecule we have indicated above, with two nuclei, and a total of 14 positive charges, and a pair of electrons about each nucleus, two more imprisoned, and a com-

plete octet in the outer shell. The CO molecule is like it, with its 14 electrons arranged as in N_2 , but with the two nuclei differently charged, being one nucleus with a positive charge of six for carbon and one with eight for oxygen, but also making a total of 14. The outer shells of these two bodies are the same, but their kernels differ. Now let us observe how these two gases resemble each other in physical properties for the very reason that their structures are so much alike.

	CO	N_2
Freezing point in deg. abs.	66	63
Boiling point in deg. abs.	81	78
Critical temperature	122	127
Critical pressure, atmospheres	35	33
Critical volume	5.05	5.17
Solubility in H_2O at 0 deg. C	3.5	2.46
Density of liquid at boiling point	0.793	0.797
Viscosity, $\eta \times 10^6$ at 0 deg. C	163	166

VII

The above is another remarkable example of physical similarity, due to what Dr. Langmuir calls isosterism; to similarity of the molecular structure of the two bodies. But in order to get what follows clearly in mind and to explain why we have pictured the N and CO molecules as tetragonal in shape rather than as spherical, let us enter into further explanation, even at the expense of repetition:

The helium atom with its nucleus and pair of electrons is the type of the innermost shell of every atom; the difference being only in that the nucleus has two positive charges, while the others, except hydrogen, have more positive charges. Since neither electron crosses the equatorial plane, we picture the atom as a nucleus, surrounded by a spherical shell, and each electron as placed within a fixed hemisphere of the shell. There is no reason to feel convinced that the electrons are held in a position of absolute stability, although we must assume that the position of each is circumscribed by the boundaries or walls of its cell. And we can well maintain that its average position is the center of its cell. When two electrons are in a cell we consider them to be placed, as to average position, one above the other, so that when, for instance, two octets are within a shell, we consider the two octets as in

FIG. 5

layers of eight. Since, according to Postulate I the central shell is divided only by an equatorial plane and the polar axis extending through the second shell and beyond is perpendicular to this equatorial plane, we have in an octet, a symmetry of electrons like that of a tetragonal crystal. Now, having conceived the atom as a sphere, it may seem an undue stretch of the imagination to call it a cube, but from the beginning we have claimed that the positions of the electrons are arranged with tetragonal symmetry. And since from now on we shall deal with electrons as they are arranged in the atoms, and since shells and cells are merely concepts of space, we shall picture every atom containing an octet as cubical in form. The octet is completed, then, when every corner of the cube contains an electron. Shells that contain more than eight electrons contain always multiples of eight cells, if we disregard those that are placed in the polar axis.

Suppose we go back for a minute to the fluorine atom with its nine electrons. There is the nucleus with its pair, and seven corners of the cube engaged. Let's make a working picture of it, Fig. 5. Then another fluorine atom will mate with it to form a molecule, as in Fig. 6. There are 16 corners of the two octets or cubes, all engaged, and each with an electron, but in two places one electron is in a corner of both cubes. The pair of electrons is shared, in other words.

VIII

Now let us develop the theory of octets which forms the basis of what Dr. Langmuir calls *covalency*, to distinguish it from valency in the generally accepted term. We shall not have much trouble here, if we address ourselves to the problem of observing how it works. The main difficulty is that we must take a new point of view, and anything new is likely to be bothersome.

The Langmuir theory of chemical combination is that these cubical atomic structures want to cover their corners with electrons so as to form complete octets. That is the way they try to complete their octets so as to settle down in life as much as possible like the inert

gases, which is the electronic ideal. And we must remember that these cubes do not connect up on their corners. One electron held in common, as in Fig. 7, never holds two atoms together. They connect up either edge to edge, or side to side, so that there is either one pair of electrons, or two pairs, held in common by two combined atoms as in Figs. 8 and 9. It is very rare that the atoms coalesce, as in nitrogen, carbon monoxide, etc., for only under pressure of grim necessity will one atom join with another, making a single cube of two. The rule is as we have stated, either in single or double pairs between two atoms.

DETERMINATION OF COVALENCY

This is covalency, and Dr. Langmuir has developed the following equation which shows us the necessary structure of the combinations from which we can determine the covalency.

$$e = 8n - 2p$$

or

$$p = \frac{8n - e}{2}$$

in which e is the total number of electrons available in the outer shells of all the atoms of a molecule; n is the number of atoms capable of forming octets, and p is the number of pairs of electrons held in common by the octets. (Postulate VIII.) Another symbol in frequent use is E , which indicates the number of available electrons in the outer shell of an atom. Available electrons means those forming incomplete octets, or, as with hydrogen, incomplete pairs. Thus, for instance, $E = 1$ for H, Li, Na, etc.; 2 for Be, Mg, etc.; 3 for B; 4 for C and Si; 5 for N and P; 6 for O and S; 7 for the halogens, and zero for the inert gases because the

octets are complete and the electrons therefore unavailable.

The equation expresses the fact for every pair of electrons held in common between octets, there is a total of two less—a decrease of two—in the number of electrons contained in the outer shell of all the atoms of a molecule. In other words, two of the electrons, the pair that is held in common by two octets, serve for the same edge in two atoms. This we explained in regard to the fluorine molecule.

COVALENCY DEFINED

The formation of molecules of compounds, therefore, depends upon the formation of octets, except in the case of hydrogen, of which the ion (which is the nucleus of this element) takes its place between two electrons. *Then the covalency of an atom is the number of pairs of electrons that it shares with adjacent atoms.* We shall soon see that covalency is not the same as valency, although covalency is in full accord with the valency theory in connection with organic compounds wherever formulas are written with carbon having a valency of 4; nitrogen 3; oxygen 2; hydrogen 1. But when it has been necessary to assume a valency of 5 for nitrogen and phosphorus; 4 or 6 for sulphur; 3, 5 or 7 for chlorine, then it gives results totally different, but in better agreement with the facts.

We can get a better idea, however, of the working of covalency by applying the rule. Let us use as our example a familiar salt, NaNO_3 . Repeating the equation

$p = \frac{8n - e}{2}$ we have one electron available from

Na which has the atomic number 11, and is therefore like neon, but with one more electron which is available in the outer shell; 5 for the nitrogen atom as we have already explained (N having atomic number 7 and so having 5 in the shell outside of its nucleus and pair) and 3 times 6, or 18, for O_3 . So: $e = 1 + 5 + 18$, or 24. There are 24 available electrons in all the atoms of the compound. Then n , or the number of atoms capable of forming octets, would be 1 for nitrogen and 3 for O_3 . Sodium with its one lone electron in the outer shell will give it up rather than gather on seven more, so Na is incapable of forming an octet. Therefore $n =$

$1 + 3$, or 4. Then $p = \frac{8n - e}{2}$ or $\frac{(8 \times 4) - 24}{2}$ or $\frac{8}{2}$ or 4.

Now let's make a picture of it in Fig. 10.

THE PLAY OF ELECTROSTATIC FORCE

Here we have two octets complete, with four pairs, held by octets in common. It provides for our NO_3 and it took an electron from the Na atom to do it, leaving the Na ion out in the cold; the Na ion being, of course, the Na atom with its one available electron extracted. But since the Na ion is positively charged we do not need any inexplicable valency to hold it on; it will stick on of itself.

The Na ion is positive because it has lost an electron which has wandered over to complete the octets in NO_3 . The Na nucleus has 11 positive charges and this ion has but 10 electrons, so it must be positive. Conversely, the NO_3 ion is a negative, because its atoms, originally electrically neutral, have taken up the extra electron from the sodium atom. To make this abundantly clear

let us note that the total positive charges on the nuclei of NO_3 (7 for N, and 3×8 for O_3) are 31, while there are 32 electrons in the ion: 24 in the shells and 8 altogether in the 4 kernels. It must be negative, therefore, with 31 positive charges and 32 electrons negatively charged. So with an opposing charge for each of the two ions, positive for that of sodium and negative for NO_3 , we have no need of other valency. The electrostatic force will hold all the positive and negative ions together, not in molecules, but built into a lattice of the entire mass, in alternate fashion, each Na ion attracting all the NO_3 ions about it, and vice versa. They do not produce molecules; they produce balanced Na^+ and NO_3^- ions, held together by electrostatic force.

When NaNO_3 is molten it becomes an electrolytic conductor, because under the influence of an electric field its ions are able to move. In solid NaNO_3 , the ions already exist, and when it is brought into contact with water the high dielectric constant of this weakens the electric field which holds the ions together, allowing them to separate, which accounts for the ready solubility of the NaNO_3 in water. And, dissolved in water, it is, of course, a good electrolytic conductor because the ions are already separated from one another.

It is interesting to note that only within the past year three remarkable papers have appeared, by Milner in England, Ghosh in India, and Bjerrum in Germany, showing from different viewpoints and from independent work that strong electrolytes are completely ionized, even in a strong solution. The octet theory leads inevitably to the above conclusion, and apparent discrepancies in the law of mass action are thus accounted for. The same method of argument applies to all salt-like substances, and in all these salts the covalency of the metal ions is zero. They do not form molecules because their ions are held together by electrostatic force and not by covalency, that is, by the sharing of pairs of electrons between them.

IX

The theory of covalency becomes simple with practice, although it lacks the *ipse dixit* quality of the valence theory. It cannot be learned by heart; in every instance it has to be reasoned out, but by the aid of the octet equation the complete picture may be rapidly visualized. We have already stated that it is in full accord with, or is the exact equivalent of, the valence theory in connection with organic compounds when the formulas are written with a valency of 4 for carbon; 3 for nitrogen; 2 for oxygen, and 1 for hydrogen, but that the results differ when it is necessary to assume a valency of 5 for nitrogen and phosphorus, 4 or 6 for sulphur; 3, 5 or 7 for chlorine. These will be explained in future papers by Dr. Langmuir, in which such compounds as those of phosphonium, sulphonium, oxonium, diazonium, etc., are particularly well accounted for. The method of application, however, is somewhat similar to that of ammonium, which we shall now consider. In the meantime we must bear in mind that 4 is the highest covalency an atom can possibly have, because no atom can engage itself with one or more others by sharing over 4 pairs to form an octet.

In NH_4Cl the octet rule shows that p (or pairs of atoms held in common) $= \frac{8n - e}{2}$ in which n (the number of atoms capable of forming octets, being Cl and N but not H) is 2, and e (or total number of all the

electrons available in all the atoms) is 7 for Cl, 5 for N, and 4 for H, or 16. So we have $p = \frac{16}{2} = 8$ or 0, so that the N and Cl atoms have no pairs in common, although each is capable of forming octets. Then the hydrogen nuclei, being positively charged because they have each lost one electron, will tend to dispose themselves, each one between two electrons on the nitrogen octet. Their electrons have gone; one to complete the chlorine octet and the remaining three to do this same with the nitrogen atom. Now these hydrogen ions can also distribute themselves, one to the chlorine atom and three to nitrogen to produce HCl and NH₃, but by attaching themselves each to the four pairs of electrons on the nitrogen ion there is achieved a greater symmetry, and the hydrogen ions will do this until the temperature is so increased as to drive the nitrogen and chlorine ions apart from each other. Then one of the hydrogen ions, having its electron taken by chlorine, will follow it, and pair off with it between two electrons, giving us NH₃ and HCl. But with ammonium chloride we have as its two parts NH₄⁺ and Cl⁻. The ammonium ion is positive for the obvious reason that, with five nuclei, there are 11 positive charges, 7 for nitrogen and 4 for H, and only 10 electrons negatively charged to match them. On the other hand, the Cl⁻ ion carries in its complete octet one more electron (taken from a hydrogen atom) than the number of positive charges on its nucleus, and therefore it is negative. The equation taught us that the number of pairs shared by octets was 0. Ammonium chloride therefore is a salt, the ions NH₄⁺ and Cl⁻ are held together by electrostatic force, and so it does not form molecules; in solution the ions become separated, and therefore it is an electrolytic conductor.

We observe from this nitrogen cube with an electron at every corner, and hydrogen ion held by every pair of electrons, that NH₃ is impossible. It also indicates why NCl₃ does not exist. NH₄⁺ is an ion, and not a compound because it contains one hydrogen nucleus that lacks its electron, which in this case went over to the chlorine atom. There is nothing to indicate a valency of 5 for nitrogen in the octet theory.

SIMILARITY OF AMMONIUM AND POTASSIUM COMPOUNDS

A curious feature of the NH₄⁺ ion is that it is surprisingly like the CH₄ molecule. They have the same number of electrons, the same structure, and they differ only in the electric charges of their respective nuclei. The hydrogen ions are held in the same way; both carbon and nitrogen forming complete octets, and both have hydrogen ion for every respective pair of electrons in the outer shell. Let us note at this point that the potassium ion—the potassium atom with one electron taken from it—is similar in structure to the argon atom except for the fact that the argon nucleus carries 18 positive charges and the potassium nucleus 19. Argon and CH₄ are very similar in their boiling points, etc. The fields of force of Ar and CH₄ are very similar, and the potassium ion differs from Ar just as the NH₄⁺ ion differs from CH₄. Now things that differ equally from similar things are similar to one another, and it stands to reason that the K ion and NH₄⁺ ion are as closely related to each other as are argon and methane. Therefore the K and NH₄ salts should be similar. And they are with remarkable frequency isomorphous in their crystal forms, and similar in their solubility and other physical characteristics. The same argument

may be used to show that the NH₄⁺ ion resembles the K ion much more closely than it does that of Na, since the Na ion has a structure like that of neon, in that it differs from it only in the electric charge of its nucleus. Ne being 10 and Na 11. Since neon does not resemble CH₄ as closely as does argon, it follows that the Na ion does not resemble the NH₄⁺ ion as closely as does that of K, and the conclusion is amply supported by the physical characteristics of their respective salts.

X

Isosterism. We have already considered pairs of substances which when found to be closely related to each other in their several structures, prove to have remarkable relationships. When two substances have the same number and arrangement of electrons they are said to be isosteric. N₂ and CO are examples and show isosteric resemblances. If, then, besides the isosteric quality they have the same total number of positive charges in their kernels (or in all the nuclei in the molecule) then we shall expect the external field of force to be approximately the same in both cases, leading to approximate identity in physical properties. If the nuclei differ in their total charge, then one of the isosteres may be electrically charged when the other is not, so that the forces around the respective molecules become very different; then most of their properties will also differ.

RELATIONSHIPS OF ISOSTERES

This subject of isosterism abounds in evidences of the reasonableness of the Langmuir postulates and we find that closely related structures show closely related physical relationships, so that we can even trace them beyond the isosteres. We have noted the similarity of structure of the CO and N₂ molecules, which are true isosteres. We have seen that because of the isosterism of CH₄ and NH₄⁺ and that of Ar and K⁺ and from the similarity of CH₄ and Ar, it follows that NH₄⁺ and K⁺ are similar, although not isosteric. We cannot compare atoms with ions, but we may reason that if Ar resembles CH₄, then an ion that is isosteric with argon will also resemble another ion that is isosteric with CH₄.

If two substances, besides being isosteres in having the same number and arrangement of their electrons, have also the same number of positive charges on the nuclei of all their atoms, then we have a right to expect the external field of force to be approximately the same in both cases, and that they will have approximately identical physical properties. On the other hand, if the positive electric charges on the nuclei of the atoms of two or more isosteric substances differ, then the forces around the respective molecules will differ, and most of their physical properties will differ. Thus the potassium ion and the argon atom, although isosteric, are differently charged, and we find them totally different in their physical and chemical properties. But we can make use of their analogies to other bodies, and thus trace out relationships which are of great aid in indicating the probable nature of these substances.

We shall give a number of instances of isosteric substances with observations made by Dr. Langmuir which will form parts of articles to appear later in the *Journal of the American Chemical Society*.

We gave early in this paper the coincidence of figures in relation to the properties of N₂O and CO₂. Now we can undertake to give the reason for them. The

octet rule shows $p = 4$ for both. So we have three cubes—three blocks, let us say—to be put together so they have four pairs of electrons or edges jointly. The simplest form would be three in a row, and we have N-O-N, or N-N-O as in Figs. 11 and 12. And we have covalences—in this case of 4 for O and 2 for N; or 4 for one N and 2 for the other N, and 2 for O. CO_2 must be O-C-O, Fig. 13, and we then have $7^+ \quad 8^+ \quad 7^+$ or 22 positive charges on the 3 nuclei.

With CO_2 we have $8^+ \quad 6^+ \quad 8^+$ also 22 positive charges on the nuclei of its 3 atoms. There are 24 corners to the three cubes, but as 4 pairs of electrons are held

FIG. 11

FIG. 12

FIG. 13

in common we need $24 - 8$ electrons, or 16 electrons, in the outer shell of each molecule—and there they are!

Let us cite a few other examples, more particularly with reference to the crystal forms: ClO_3^- , SO_4^{--} and PO_4^{--} . These are isosteric, therefore we should find similarities in the crystals of their salts. Investigation brings out the following: CaHPO_4 and NaHSO_4 crystallize in triclinic pinacoids, showing the following axes and angles of their axes:

	a	b	c	α	β	γ
CaHPO_4	0.6467	1	0.8244	$84^\circ 57'$	$89^\circ 43'$	$85^\circ 38'$
NaHSO_4	0.646	1	0.837	$85^\circ 06'$	$88^\circ 57'$	$86^\circ 47'$

or almost wholly within the limit of experimental error, notwithstanding the marked difference in solubilities and similar physical properties.

These observations infuse life into Groth's otherwise dreary *Chemische Kristallographie*.

Again, KClO_4 and SrSO_4 are isosteric; they belong to the orthorhombic system, and show the following ratios of their axes:

	a	b	c
KClO_4	0.7817	1	1.2798
SrSO_4	0.7790	1	1.2802

Double refraction is positive in both and they show the same cleavages. They are, as are the others, typical cases of isomorphism, and thus afford direct experimental proof that KClO_4 and SrSO_4 have similar constitutions. The octet theory indicates that the central atom in both compounds has a covalency of 4. The usual viewpoint of the chemist is that the valency of Cl in KClO_4 is 7, while that of sulphur in SrSO_4 is 6. But the fact that these compounds are isomorphous encourages the belief that the rutinary theory with valencies of 7 for Cl and 6 for S is wrong.

ISOSTERIC NATURE OF APPARENTLY UNRELATED COMPOUNDS

Here follow more preliminary notes, to be dealt with in detail later by Dr. Langmuir:

SrHPO_4 and KHSO_4 are orthorhombic-pyramidal in form; their angles of axes are:

	a	b	c
SrHPO_4	0.8607	1	1.9344
KHSO_4	0.8581	1	1.9431

The optical axis in each is in (001) plane, and the habitus of the crystal forms are practically identical.

NaF and MgO are isosteric and are isomorphous in

their crystal structures, according to measurements recently made by the X-ray method by Dr. Hull.

Corresponding salts of HN_3 and HCNO are isosteric, and the data in the literature, as far as they go, show that their solubilities are the same.

KN_3 and KCNO are both tetragonal: their ratios of axes are below:

KN_3	1 : 0.5798
KCNO	1 : 0.5766

Both give strong negative double refraction, and both have (001) and (111) as their most common crystal faces.

Let us conclude the list with mentioning a couple of salts that never were supposed to show any twin-like qualities: $\text{Na}^+ \text{NO}_3^-$ and $\text{Ca}^{++} \text{CO}_3^{--}$ which are almost identical in crystalline form, optical properties and cleavage. This is now accounted for by the fact that the NO_3^- and CO_3^{--} ions are isosteric. Since the force holding the Ca^{++} and CO_3^{--} ions together is four times as great as that holding Na^+ to NO_3^- it is more difficult to separate the ions, from which we understand why CaCO_3 is but slightly soluble, whereas in NaNO_3 the ions are easily separated in such a dielectric solvent as water, and that when the ions are separated, NaNO_3 becomes an electrolytic conductor.

XI

The theory, as may be observed, opens up vast possibilities. We can imagine periods of perplexity and dizziness after we have tried with sticks and balls of wax to build up atoms and molecules in the almost infinite number of chemical possibilities and we almost dread the task. It is usually difficult to present things of three dimensions in drawings of two, and the Langmuir atoms and molecules and compounds are all of three dimensions. We may have been somewhat negligent of this concept rather than ignorant of it in our methods heretofore. Whether this generation will take its chemistry in cubical atoms and build up its molecules and compounds in block-houses according to these postulates rests in the lap of the future for determination, but we think them too full of promise to be neglected for years as was Willard Gibbs' phase rule. We regard the work as a contribution of the first moment to the science of chemistry. And we believe that, as they are developed and revised and applied in practice, they will become familiar and easy of comprehension. We subjoin a revised list as of the postulates prepared for a forthcoming article on the subject by the author of the system.

XII

THE LANGMUIR POSTULATES

I—The electrons in atoms are either stationary, or rotate, revolve, or oscillate about definite positions in the atom. The electrons in the most stable atoms; namely, those of the inert gases, have positions symmetrical with respect to a plane passing through the nucleus at the center of the atom. No electrons lie in the equatorial plane. There is an axis of symmetry (polar axis) perpendicular to the equatorial plane through which four secondary planes of symmetry pass, forming angles of 45° deg. with one another. These atoms thus have the symmetry of a tetragonal crystal.

II—The electrons in any given atom are distributed through a series of concentric (nearly) spherical shells, all of equal thickness. Thus the mean radii of the shells

form an arithmetic series 1, 2, 3, 4, and the effective areas are in the ratios 1; 2²; 3²; 4².

III—Each shell is divided into cellular spaces or cells, occupying equal areas in their respective shells, and distributed over the surface of the shells according to the symmetry required by Postulate 1. The first shell thus contains 2 cells, the second, 8; the third, 18, and the fourth 32.

IV—Each of the cells in the first shell can contain only one electron, but each other cell can contain either one or two. All the inner shells must have their full quotas of electrons before the outer shells can contain any. No cell in the outside layer can contain two electrons until all the other cells in this layer contain at least one.

V—When the number of electrons in the outside layer is small these electrons arrange themselves over the underlying ones, being acted on by magnetic attractive forces. But as the charge on the kernel or the number of electrons in the outside layer increases, the electrostatic repulsion of the underlying electrons becomes predominant, and the outer electrons then tend to rearrange themselves so as to be as far as possible from the underlying ones.

VI—The most stable arrangement of electrons is that of the pair in the helium atom. A stable pair may also be held by: (a) a single nucleus; (b) two hydrogen nuclei; (c) a hydrogen nucleus and the kernel of another atom; (d) two atomic kernels (very rare).

VII—The next most stable arrangement of atoms is the octet, that is, a group of electrons like that in the second shell of the neon atom. Any atom with the atomic number less than 18 and which had more than three electrons in its outside layer tends to take up enough electrons to complete its octet.

VIII—Two octets may hold one, two or sometimes three pairs of electrons in common. One octet may share one, two, three or four pairs of its electrons with one, two, three or four other octets. One or more pairs of electrons in an octet may be shared by the corresponding number of hydrogen nuclei. No electron can be shared by more than two octets.

History of Prices During the War

The Price Section of the War Industries Board is preparing a series of bulletins covering thoroughly the whole field of prices from the beginning of 1913 to the end of 1918. These bulletins will be completed and issued as soon as possible.

There will be 57 in all, the first seven being of a general nature. Each of the remaining fifty will be devoted to an important industry and of these the following (numbered from 30 to 57 in the order given) will be of interest to chemists and metallurgists:

Rubber and rubber products; paper; fibers and fiber products; iron, steel and their products; ferro-alloys, non-ferrous and rare metals; coal and coke; petroleum and petroleum products; matches; clay products; sand and gravel; quarry products; cement; glass; lumber; paints and varnishes; mineral acids; heavy chemicals; miscellaneous inorganic chemicals; fertilizers; soaps and glycerine; essential oils, flavoring and perfumery materials; wood distillation products and naval stores; natural dyestuffs and tanning chemicals; coal tar crudes, intermediates and dyes; drugs and pharmaceuticals; proprietary preparations; explosives; miscellaneous organic chemicals.

Melting Point of Asphalts

BY LELAND M. PROCTOR

AS ASPHALTS or bituminous materials are not true chemical compounds, but rather an intimate mixture of a large number of different compounds, they have no definite melting points. That is, there is no critical temperature which can be observed at which they pass from a solid to a liquid state. Therefore, a stated melting point will depend upon the method used and the conditions under which it is observed, and is purely arbitrary. Each method will give a different temperature for the melting point, and thus the method should always be given when writing of the characteristics of bituminous substances.

The following data were obtained on asphalts manufactured: No. 1, from Mid-Continent residual oil; No. 2, from a mixture of Mid-Continent and Mexican residual oils; No. 3, from Mexican residual oil; and No. 4, from a mixture of Mexican residual oil and residual oil from the Burton process. These asphalts have very different physical characteristics apparent to the casual observer. Four different methods, the Richardson ball, or over mercury, method, the General Electric method, the Kramer and Sarnow method and the ball and ring method, were used for these tests.

TABLE OF CHEMICAL AND PHYSICAL CHARACTERISTICS

The following table of chemical and physical characteristics will give a much better conception of the asphalts used:

	No. 1	No. 2	No. 3	No. 4
Carbon tetrachloride soluble...	98.79	98.47	99.05	82.90
Carbon bisulphide soluble...	99.87	98.94	99.47	97.59
Ethyl ether soluble...	75.82	71.95	67.28	69.71
Naphtha soluble, 88 deg. F...	87.50	76.45	96.28	77.56
Fixed carbon...	17.78	19.57	24.44	28.40
Mineral matter as ash...	0.14	0.048	0.421	0.163
Penetration at 77 deg. F., 100 g., 5 sec.	23	17	13	3
Ductility at 77 deg. F. in cm.	2.00	3.20	3.2	0.10
Sp. gr. at 77 deg. F.	1.0026	1.028	1.054	1.135
Flash point (open cup)	506	466	471	444
Burn point (open cup)	582	584	558	519

A short description of each method follows. It is not the aim here to give them in any great detail, as these can be more accurately obtained from some of the few good texts on the subject of bitumens. Failing access to these, however, they are given sufficiently fully to enable one to carry out the operations and to obtain results which will be accurate within the limits of manufacturing.

THE RICHARDSON BALL OR OVER MERCURY METHOD

The apparatus consists of 150 cc. beaker about half filled with mercury, mounted on an iron stand, with a thermometer suspended so that the bulb is immersed in the mercury. On the surface of the mercury is placed a microscope slide, thus forming a mirror. The sample of asphalt is rolled into a sphere about the size of a French pea, heating, if necessary, to free from all nicks and creases. This is placed on the microscope slide and the top of the beaker covered with a cardboard to protect the sample from drafts. Heat is applied in such quantity that the temperature is raised at the rate of 10 deg. F. per minute. When the ball is first placed on the slide it appears with its reflection as two spheres, one over the other, touching at a single point, but as the temperature rises it gradually flattens out on the bottom until the melting point is reached, which is the point at which the half round sample and its reflection make a single sphere.

AVERAGE EQUIVALENT MELTING POINTS BY K & S. BALL & RING, G. E. AND RICHARDSON TESTS ON FOUR ASPHALTS

THE GENERAL ELECTRIC METHOD

A small quantity of the asphalt is melted and the bulb of a thermometer immersed in the liquid, withdrawn, and while the asphalt is cooling the thermometer is rotated horizontally. The process is repeated until enough material adheres, when it is rolled on an amalgamated brass plate, until a cylinder slightly smaller than a pencil is obtained. With a hot knife the lower end is cut off so that it is of uniform thickness throughout. The thermometer is now inserted in a cork, cut so as to reveal the graduations on the thermometer scale, and placed in a test tube so that the end of the thermometer is one inch from the bottom of the tube, and the whole is placed in a sulphuric acid or a glycerine bath so that the level of the liquid is above the top of the sample in the thermometer. Heat is then applied in such quantity that the temperature rises 5 deg. F. per minute. As the temperature rises gradually the sample slips on the thermometer and the point at which it first touches the bottom of the test tube is taken as the melting point.

THE KRAMER AND SARNOW METHOD

A small quantity of asphalt is melted in a suitable dish and the end of a glass tube 5 mm. inside diameter and about 8 cm. in length is thrust in to a depth of about 7 mm., withdrawn and the asphalt allowed to cool while the tube is rotated horizontally. When the asphalt is sufficiently cooled so that it no longer flows, the asphalt adhering to the outside of the tube is cleaned away and 5 g. of mercury is placed on the asphalt in the tube. The tube is secured to the thermometer so that the sample and bulb are at the same level, and both are suspended in a glycerine bath. Heat is applied in such quantity as to rise at the rate of 4 deg. F. per minute. As the temperature rises the mercury gradually sinks out of

sight, forming a pocket, and the point at which it breaks through and falls to the bottom of the beaker is taken as the melting point.

THE BALL AND RING METHOD

The ball is polished steel, $\frac{3}{8}$ in. in diameter, weighing between 3.45 and 3.5 g. The ring is of brass, $\frac{3}{8}$ in. inside diameter, $\frac{1}{4}$ in. deep, with walls $\frac{3}{16}$ in. thick, fastened at right angles to a wire. A small quantity of asphalt is melted in a tablespoon and poured into the ring, which is set on an amalgamated brass plate, allowing for shrinkage. When it is cool the excess is cut off with a hot knife and the ball set on the asphalt in the ring. The wire is inserted in one hole of a two-hole cork and through the other a thermometer is inserted so that the bulb is at the same level as the ring, and the whole is suspended in a glycerine bath 1 in. above the bottom of the beaker. Heat is applied in sufficient quantity to raise the temperature at the rate of 10 deg. F. As it is heated the ball gradually sinks into the asphalt, coming through and forming a pocket with the ball inside. The temperature at which the pocket touches the bottom of the beaker is taken as the melting point.

COMPARATIVE DETERMINATIONS

As will readily be seen, there is no relation between the melting point as specified by one method and that of another method, each giving a different temperature.

Sample	FIRST TEST			
	Richardson Ball	General Electric	Kramer and Sarnow	Ball and Ring
No. 1	275	271	214	246
No. 2	225	203	141	174
No. 3	271	236	191	219
No. 4	236	214	175	198
Sample	SECOND TEST			
	Richardson Ball	General Electric	Kramer and Sarnow	Ball and Ring
No. 1	275	266	233	249
No. 2	224	193	152	187
No. 3	273	243	196	214
No. 4	239	205	181	204
Sample	THIRD TEST			
	Richardson Ball	General Electric	Kramer and Sarnow	Ball and Ring
No. 1	277	274	223	248
No. 2	226	202	156	190
No. 3	276	242	200	226
No. 4	243	208	186	204
Sample	AVERAGE			
	Richardson Ball	General Electric	Kramer and Sarnow	Ball and Ring
No. 1	276	270	223	247
No. 2	225	199	149	184
No. 3	273	240	196	220
No. 4	239	209	181	202

A study of the tables shows this fact very strikingly, that there is a decided difference in the melting points as taken by the different methods and also that for any two asphalts having different characteristics the difference is not the same. Thus, taking the method giving the highest results, the Richardson ball method, the following table of differences can be obtained:

Asphalt	ΔT Richardson Ball and General Electric, Deg.	ΔT Richardson Ball and Kramer and Sarnow, Deg.	ΔT Richardson Ball and Ball and Ring, Deg.
No. 1	6	53	29
No. 2	26	76	41
No. 3	33	77	53
No. 4	30	58	27

This variation can be accredited only to the difference in the character of the asphalts. No. 1 is a short fibered, comparatively soft, very slow melting paraffine base asphalt greasy to the touch. No. 2 is a long fibered, soft, tenacious, slow melting mixed base asphalt. No. 3 is a long fibered, comparatively hard, tough asphalt base asphalt. No. 4 is a hard, brittle, shining bright, quick melting, mixed base asphalt.

The Richardson ball method gives very close checks, is rapid, simple and several different samples can be run at the same time. It can be taught very easily to the ordinary workman and thus lends itself nicely to the purposes of factory control. The apparatus can be easily cleaned by dipping the slide into the mercury while hot and wiping with a cloth. It has this disadvantage, the personal error enters in to a greater extent than in any others in the matter of judging when the ball is completely down and in estimating the size of the sample.

The General Electric method gives fair checks, but is unsuited to factory control on account of the slowness—only one can be taken at a time unless a number of thermometers and tubes are used—and the work of cleaning the tube is tedious. The personal error enters in the rolling of the cylinder on the thermometer to a little less than the size of a pencil.

The Kramer and Sarnow method gives rather the

poorest checks of these four methods, though some texts credit it with far greater accuracy than was obtained in these tests. The method is more or less complicated and tedious, taking more apparatus than any of the others in that the mercury must be weighed out within reasonable limits. As many different samples may be tested as can be conveniently observed at the same time, but this advantage is balanced by the time necessary to clean the apparatus.

The ball and ring method has been adopted by the American Society for Testing Materials as a standard for this class of materials, and gives very good checks. The method is well adapted to specifications, because when the conditions are standardized the results may easily be duplicated by any other observer, the personal error being practically eliminated. It is not, however, very well adapted to factory control, as but one sample can be tested at a time.

Lockland, Ohio.

The Explosion of Chemicals—I Common Law Liability

BY CHESLA C. SHERLOCK

THE legal liability of an employer for injuries caused to his workmen by means of the explosions of chemicals which they are required by the duties of employment to work with must necessarily divide itself into two classifications—common law liability and the liability under the workmen's compensation acts. While the common law liability is not so generally operative as it was a few years ago, it still remains in many jurisdictions, so a consideration of the question can by no means be complete without first discussing it. Besides, the workmen's compensation system springs out of the common law system and its abuses, so that a complete understanding of the common law liability is necessary before any light can be cast upon the liability under the compensation acts.

Under the common law, it was a settled principle that the employer should provide his workmen with a reasonably safe place in which to work, safe appliances and tools and give them competent instruction in the use of such tools and as to the best manner of carrying on the work to be done. Furthermore, if the employer, by reason of his superior knowledge or position to acquire knowledge, should know of facts which might endanger the workman, it was his duty to warn the workman of these dangers and risks, especially in the case where the workman was young, inexperienced or new at the work.

In the case of dangerous tools or appliances or materials complicated in nature, it was the duty of the employer to exercise care and caution to keep them in a state of repair or to handle them in such manner that they did not become dangerous through defective condition or operation to the workman. If the employer lagged in this respect, he was very apt to find himself guilty of negligence and liable in an action for damages to the injured workman.

On the other hand, through long continued following of precedents and customs in determining what the law was, a great maze of decisions raised a barrier around the injured workman so that in obtaining his recovery he was put to such lengths that it was practically impossible for the average workman to realize anything

for his injuries. What he did recover generally went for the costs of litigation and attorneys' fees.

Among these rules, the common law held that if a workman were guilty of contributory negligence, no matter how slight that negligence might be, he could not recover damages from his employer for the injuries suffered. If he was injured by the negligence of a fellow servant, he could not recover from the employer for the injury sustained, because the employer could not be held responsible for the negligence of another person, even though that person were his employee. If the workman was injured in the course of his employment by some risk incident to the employment, he was considered to have assumed the risk and could not recover.

These were the main rules of the common law applicable to employers and their employees. We will now consider them in the light of decisions handed down by the courts in specific cases dealing with the explosion of chemicals.

In an Iowa case, a drug clerk was mixing a compound of explosive nature. He ascended his ladder to get another ingredient, leaving the mixture on the shelf below. The mixture being compounded was explosive only to force or blows. He failed to tell another clerk who was working at a soda fountain of the dangers lurking in the compound. The latter went to the mixture and attempted to stir it. An explosion occurred injuring the latter. He sought damages.

The court held that "No duty which a druggist owes his employees with respect to furnishing a safe place to work is violated by leaving a mixture which is being compounded by an experienced pharmacist and is explosive under a blow or force in an open mortar while the one at work upon it ascends a ladder to secure other chemicals." The court also held that the employer was not guilty of negligence for a failure to warn the clerk at the soda fountain of the dangers attending the mixture.

In a Michigan case, a flashlight mixture was being compounded. The employee stated that, as usual, in preparing the mixture, he mixed together equal parts of powder and magnesium, when in some unaccountable manner the mixture exploded. The evidence tended to disclose the fact that powder and magnesium are not explosive and that the combination of the two when mixed in equal parts was not explosive, that they would not and never had exploded in the experience of the wit-

nesses. The court was of the opinion that some substitute had been used in place of the magnesium and held that it was for the jury to determine. An award had been made by the lower court in favor of the employer, but this decision was reversed.

In a Missouri case, it was claimed that the employer had been guilty of negligence in permitting an employee to put potassium in water during a fire, whereby the explosion resulted, injuring the plaintiff. Said the court: "The plaintiff could not close his eyes upon all that was going on around him or turn a deaf ear to the shouts of danger that went up from the defendant's manager and the bystanders around him, and yet hold the defendant liable because he did not actually see or hear the warning. . . . The instruction should have submitted the issue whether the plaintiff ought to have known the danger in which he was standing, in view of all the facts and circumstances, and not have been confined to what he actually knew, as was done by the one given."

In a New York case, it was shown that a taxidermist employed by the defendant company had poured a mixture of carbon disulphide, a disinfectant, into a bird case, containing electric wires. These wires produced a spark, which ignited the fumes and caused an explosion injuring another who was assisting him. The court held that apart from the statute, the plaintiff had an action at common law for damages.

Among other things, the court said: "It was the plaintiff's duty to assist at the service, and he had used the same material on other occasions, but did not know of the danger of using it in large quantity where there was an electric current, especially running through two twisted wires, the installation of which could be affected by the chemical, so as to permit a short circuit. It was the duty of the employer to know that, and to instruct as to the use of it and warn its agents and employees of the danger. But the plaintiff was committed to the work unwarned. There was a latent danger dependent upon a knowledge of scientific facts, which it was the duty of the employer to have and impart to its servants.

"Although plaintiff had served before in the use of the chemical, here entered a new factor, and as to that a new and more perilous service was introduced and the plaintiff should have been instructed, although he was new only to the increased risk of the service. . . . The manner of use was changed and a new element of danger introduced and yet the plaintiff was unwarned."

EMPLOYER MUST WARN WORKMAN

In this case, we find the employer being held liable to the employee for the injuries suffered because the employer failed to issue the warnings which his superior knowledge told him, or ought to have told him, should be given to the workman.

In a Missouri case, the workman had been given a can, supposedly empty, but which contained wood alcohol, and was told to solder the tip end of a spout. He attempted to carry out these orders, but when his blow torch came in contact with the alcohol it caused an explosion which caused the injuries complained of. The employer was held guilty of actionable negligence.

In a Massachusetts case, the superintendent of the employing company had a choice of safe and dangerous materials in cleaning out the interior of a boiler, but instructed the plaintiff to use naphtha. The latter at-

tempted to do so, but the fumes came in contact with a lamp which he was carrying, resulting in the explosion, causing the injury complained of. The employer was held not liable, because the court was of the opinion that the superintendent was a fellow servant of the injured workman, and because the danger to which the workman was exposed was merely a transitory one, existing only on the single occasion when the injury was sustained, and due to no fault of plan or construction, or lack of repair, and no permanent defect or want of safety in the defendant's works or in the manner in which they had been ordinarily used.

In a Michigan case, the workman was directed by his employer to help put out a fire and was injured by the explosion of a barrel of paint containing benzine. Judgment was given in the lower court for the plaintiff, but this was reversed, the injuries received being regarded more as an accident than as the result of negligence. The court also held that keeping a barrel of paint on the premises was not negligence, although fire was not improbable. It was not in and of itself dangerous, nor was its presence or its use attended with danger, in the absence of the agency.

The court said: "This is not a case of insecure place or defective appliances, nor is it one where the servant was ordered into another branch of the ordinary service in which there were increased hazards. . . . The dangers ordinarily incident to a fire are obvious to persons of mature years. Employer and employees are equally conscious of such danger, and ordinarily equally skilled in the means employed to extinguish a fire. The work of extinguishment is usually attended with danger, and explosions are not uncommon. The law recognizes a fire as one of the perils which excuse acts otherwise illegal."

In a New York case, the employer directed his servant to thrust his hand into a waste pipe, whereby the hand and the arm of the servant were badly burned by a solution of potash which had been thrown into the pipe without the servant's knowledge and prior to his employment. The court held that the master's order was an assurance that it was safe for the employee to do so, and that the master was chargeable with negligence for not having exercised ordinary care before giving such assurance. The court also said that it was the employer's duty to furnish the servant from the outstart with a place to work in as reasonably safe and free from the risk of injury as the character of the employment would permit, or, before assigning him to work, to call his attention to such lurking dangers as in the exercise of ordinary prudence the former would have been able to discover. The duty was somewhat further intensified, in the opinion of the court, because of the youth and inexperience of the workman.

The employer must not come to the conclusion that these common law principles and decisions are by any means out of date and not applicable to cases to-day. The fact is, as was mentioned before, a great many of the States have not departed from the common law practice in the least particular. Then, in many of the States having workmen's compensation legislation, thousands of workmen are not covered by such legislation. This means that the common law still applies to them in case of injury. Keeping these points in mind will serve to benefit many employers.

Thermo-Electric Pyrometers for Plant Use

BY A. O. ASEMAN

THE most widely used pyrometer for general metallurgical operations is the thermo-electric pyrometer. Its popularity is due in part to its cheapness, robustness, ease of observation, and availability for automatically making a permanent record. It can also be used over a wider range than any other form of pyrometer, giving readings of extreme accuracy from the boiling point of liquid air (-193 deg. C.) to the melting point of palladium (1550 deg. C.).

In what follows, this pyrometer will be treated strictly from an industrial viewpoint. The following nomenclature for the various parts is now almost universally used. The two unlike wires giving rise to an e.m.f. when heated are known as a thermo-element or thermocouple, or simply couple. The couple, suitably insulated, complete with mounting and protecting tubes, is known as a fire-end. The galvanometer for measuring the e.m.f. developed is known as a millivoltmeter or potentiometer, and may be recording. If this instrument is graduated to read temperature direct, it is known as an indicator. The couple and galvanometer together are called a thermo-electric pyrometer or recording pyrometer as the case may be.

THERMOCOUPLES

Thermocouples are divided into two classes, namely, rare or noble metal, and base metal couples.

Of the rare metal class the Le Chatelier couple, composed of one wire ($-$) of pure platinum, and the other ($+$) of an alloy of 90 per cent platinum and 10 per cent rhodium, is the only one in general use. The two chief manufacturers of this couple are Johnson Matthey & Co. of London and Heraeus of Germany. Charles Engelhard of New York is now producing the Heraeus platinum in this country according to the original process. The Johnson Matthey & Co. platinum has a slightly higher thermo-electric power, but is not constant from year to year. The Heraeus platinum has maintained a constant calibration for many years, and is to be recommended of the two. It also exhibits less tendency to crystallize. The 90 Pt-10 Ir couple was popular for some time and is still used in places, as it has about 50 per cent higher thermo-electric power. Its use, however, is not to be recommended, as heating distills the iridium rapidly, thereby changing its calibration. Tests show a change of over 13 per cent from heating at 1100 deg. C. for eight hours.

Of the base metal couples there are a number in general use. These have a higher thermo-electric power, and are cheaper at first cost, but owing to their rapid deterioration, especially at the higher temperatures, it is often cheaper to use the more expensive rare metal couples. The higher thermo-electric power, however (being from four to six times that of the rare metal couples), is a decided advantage, as it permits the use of more robust indicating and recording instruments. The advantage of this for plant use is apparent.

Fig. 1 shows the temperature millivolt relation for the principal types of couples on the market to-day. The upper limit to which these couples can be used continuously is indicated by the termination of the curve. The chromel-alumel couples are useful at higher temperature than any other base metal couple, but are considerably more expensive. The temperature e.m.f. relation for most couples is rather complex, but can be closely approximated by the parabolic formula

$$E = a + bt + ct^2 \quad (1)$$

or

$$E = ab + bt^2 \quad (2)$$

In the case of most base metal couples, the curve approaches so closely to a straight line that for all practical purposes a linear equation holds

$$E = a + bt \quad (3)$$

A couple is calibrated by observing the e.m.f. generated at one or more fixed points, and substituting these values in the corresponding formula and solving in the usual way. A more convenient method is to plot these points graphically and draw a smooth curve fitting all points.

As a general rule a couple should not be exposed directly to a high temperature, on account of its susceptibility to contaminating influences such as reducing gases, metallic vapors, silica, and other agents which al-

FIG. 1. TEMPERATURE-MILLIVOLT RELATION FOR THE PRINCIPAL TYPES OF COUPLES

ter its thermo-electric characteristics. This is taken care of by enclosing the couple in suitable protecting tubes. Often two protecting tubes are used, distinguished as primary and secondary. The primary protection is impervious to gas and may be either a glazed porcelain, silica or metal tube.

Porcelain is capable of standing a higher temperature, being used above 1200 deg. C. under constant temperature conditions. The porcelain available now has such a high temperature coefficient that it will not stand up under varying temperature. It has recently been announced that a pyrometer maker in this country has succeeded in making porcelain pyrometer tubes with a much lower coefficient of expansion, but up to the time of writing this we have been unable to try them out.

Silica can be used continuously up to 1100 deg. C. or for a short time to higher temperatures. At 1200 deg. C. or higher it devitrifies rapidly, becoming porous and losing its mechanical strength. Metal sheaths are usually of iron or steel, the properties of which are too well known to need special mention.

The secondary protection is used to give mechanical strength to the fire-end or to protect the primary from the action of corrosive vapors or metals. Zinc vapor is especially corrosive in porcelain. The materials most commonly used are fire clay, nickel chromium alloys, calorized steel or carborundum tubes.

The best manner of insulating the two wires is by means of a double bored insulating tube. This is very

desirable when silica protecting tubes are used, as it is important that the wires (especially rare metal wires) do not come in contact with the silica.

It is desirable for plant use to mount the couple so that it, with its protecting tubes, will be firmly held together. This is usually done with suitable pipe fittings. Fig. 2 shows several forms of mountings with various accessories for portable and permanent use.

GALVANOMETERS

The question of the instrument for reading the couple e.m.f. is one which deserves considerable thought. The tendency in instrument construction of the galvanometer type is to make as high a resistance as is consistent with making it sufficiently robust to stand up under plant usage. Instruments of this type are connected ammeter-like in series with the thermocouple. The thermo-electric current generated is small and is affected by any change in the resistance of the circuit. By using high-resistance instruments the change in the external circuit is a small part of the total resistance. Thus take the case of two galvanometers, one with an internal resistance of 5 ohms and one of 300 ohms, both calibrated to read correct for an external resistance of 2 ohms. Suppose that in each case the external resistance is increased by 0.8 ohm by changing the depth of immersion of the couple, or increasing the length of leads. The error due to the external resistance is equal to the resistance of the galvanometer plus the fixed external resistance, divided by the sum of the total resistance of the circuit.

$$\text{Then } \frac{300 + 2}{300 + 2 + 0.8} = 0.997 \text{ or } - 0.3 \text{ of 1 per cent}$$

$$\text{and } \frac{5 + 2}{5 + 2 + 0.8} = 0.897 \text{ or } - 10.3 \text{ per cent.}$$

A change of 0.8 ohm in the case of the 300-ohm instrument is quite negligible, while in the case of the 5-ohm instrument it is far from so, even for rough work. These are not exaggerated cases, but are constantly met with in everyday practice. It is quite evident, then, that the use of low-resistance instruments should be discouraged.

In an attempt to eliminate the effects of a variable external resistance, such instruments as the portable potentiometer and pyrovoltmeter have been developed. The readings of these instruments are independent of the external resistance. They are excellent instruments and recommended for use wherever possible. They are, however, open to the objection that they do not give continuous indications, and require a certain skill to operate. Also they cannot conveniently be made recording. There is a recording potentiometer on the market, but it is more of a laboratory than plant instrument. The readings of a potentiometer cannot be relied on in extreme weather.

Special mention may be made of the Engelhard double suspension instrument and the Wilson-Maeulen unipivot instrument, both embodying features not found in ordinary galvanometer millivoltmeters. The former has no pivots, the moving coil being suspended by two delicate ribbons under tension. This has an extremely high resistance, but has the disadvantage of a shifting zero every time the position of the instrument is changed. It is also very susceptible to vibrations. The unipivot instrument has, as the name implies, only one pivot, which is at the center of gravity of the moving element. This is a very robust instrument, and is the

FIG. 2

Forms of portable and permanent mountings, primary and secondary protecting tubes, insulating tubes, cold junction extension wire, and water cooled cold junction devices.

only one on the market for portable use in which the pivot can be removed from the jewel while transporting from place to place. This is a valuable feature, as it has been our experience that these instruments are usually damaged while being ported about rather than when in use. It is evident that, although the weight of a moving element is small, when the entire weight is concentrated on a point there may be a pressure of several thousand pounds per square inch, in which case it does not require a very hard jolt to puncture the jewel. Of course most instruments are magnetically damped, but this only prevents rotation, and does not prevent the harmful sudden stresses on the jewels.

COLD JUNCTION

Attention should be called to the cold junction correction, since there is a notable tendency to neglect this important consideration. The e.m.f. developed by a couple depends on the difference in temperature between the hot and cold junctions, as well as the actual temperature of each. In calibrating a couple, therefore, the cold junction is maintained at some definite temperature, usually 0 deg. C. In practice it is oftentimes convenient to maintain the cold junction at a temperature other than that at which the couple has been calibrated, in which case the reading must be modified by a "cold junction correction." The correction is equal to the change in temperature multiplied by a factor.

$$\text{Cor.} = (t_c - t_0) K \quad (4)$$

t_c = operating temperature of cold junction

t_0 = calibration temperature of cold junction (0 deg. C.)

K = factor depending on couple.

If the indications are obtained in millivolts, it is only necessary to add to the observed e.m.f. the value of the e.m.f. developed when the cold junction is at 0 deg. C. and the hot junction is at t_c deg. If the indications are obtained in degrees, the correction must be made in degrees. For a Pt, Pt-Rh thermocouple, K , in formula (4) is 0.6 when hot junction is from 400 to 700 deg. and 0.5 when hot junction is between 700 and 1400 deg. C. In the case of base metal couples, the calibration curve of which is approximately a straight line, K is equal to 1.0.

A number of schemes and devices have appeared for keeping the cold junction temperature constant, or automatically compensating for same. One convenient method is by use of cold junction extension leads, whereby the junction can be removed to a region of more uniform temperature. These leads may or may not be of the same material as the couple, but they do have the same thermo-electric characteristics as the couple. In permanent installations one method is to bury the cold junction by driving a pipe pointed at one end 10 to 12 ft. in the ground, at which point the temperature remains constant throughout the year. Another plan is to water-cool the cold junction by means of running water. Still another is to lead the cold junction to a thermostatic controlled constant temperature box. There are numerous other devices, each having certain advantages and disadvantages. The methods described above merely keep the cold junction temperature constant. Those which compensate for a changing temperature are complicated, delicate and very likely to get out of order, so their use should be avoided.

Calibrations of thermocouples are spoken of as primary and secondary. Primary calibrations are made

by noting the e.m.f. generated by a couple immersed in a pure substance, when at its melting point. Observations taken at regular time intervals show no change in temperature while the substance is melting. The melting point, which is very accurately known, serves as a fixed point at which couple e.m.f. can be read. Some of the commonly used fixed points are:

	deg. C.
Melting point of ice	0
Melting point of tin	232
Melting point of zinc	419
Melting point of salt (NaCl)	801

To calibrate a couple, then, it is necessary to observe the e.m.f. generated when the hot junction is exposed to the melting point temperatures of several of the above fixed points. A calibration curve can then be

FIG. 3. METHODS OF MAINTAINING COLD JUNCTION AT CONSTANT TEMPERATURE

made by plotting the known melting temperatures as ordinates, and the corresponding e.m.f. in millivolts as abscissas, as in Fig. 1.

By use of calibration curves similar to those shown in Fig. 1, it is possible to completely calibrate a couple, by simply taking a zinc point, and plotting this point with the corresponding curve for that couple. A curve drawn through the point and having the same shape as the standard curve will be the calibration of the couple.

The zinc point may be taken in the following manner: A crucible is made from a piece of 2-in. wrought iron pipe 8 to 10 in. long with a cap on one end. This is filled with "Horsehead" zinc and melted, and the couple, suitably protected, immersed in it. The whole is then allowed to cool, and readings made every half minute. The freezing point is taken when the couple indication does not change perceptibly over a period of 5 to 10 or more readings. It is best to protect the couple by a closed steel tube. Porcelain should never be directly exposed to molten or vaporized zinc.

Secondary calibrations are made by comparing the couple to another which has already been calibrated by primary calibration. This is best done by enclosing both couples, suitably insulated, in an iron pipe and heating the pipe in a furnace. Indications of both couples can be made on the same instrument by means of a double throw switch.

Generally speaking, it is better when possible to have calibrations made in a laboratory equipped for that purpose. All couples and instruments should be checked frequently.

Manufacturing Plant of the Providence Gas Co.—II*

Description of the Installation and Operation of the New Water Gas and Producer Gas Plants at Sassafras Point—Water and Producer Gas Machinery and Apparatus, Measuring and Recording Instruments

BY WALTER M. RUSSELL

IN THE water gas plant three 11-ft. 6-in. U.G.I. standard carbureted water gas machines were installed. (Fig. 9.)

Air for blasting is provided individually for each machine, but by means of a manifold any one of the three blowers may serve the machines. In routine operations, one blower serves one machine only. The blowers were furnished by the Rateau-Battu-Smoot Co. and consist of standard Rateau steam turbines, each driving two birotor blowers, there being two impellers within a single casing acting in parallel, the inlet and discharge connections being connected in parallel with a single orifice in each case. The radial impeller blades are dovetailed into a heavy steel shaft. Volutes feed suction air to the impellers and after leaving the impellers the air enters the diffusion chamber, wherein discharge velocity is converted into pressure. The blower casing is parted on the horizontal center line, inlet and outlet nozzles being located in the lower half. These blowers operate at comparatively high speed—about 7500 r.p.m.—and, as the blower shaft is so designed as not to pass through its critical speed, the blowers may be stopped and started at frequent intervals, it being possible to bring them from rest to full speed in 10 sec. after having been heated up. Because of the high speed, great care had to be taken in designing the lubrication. The bearings are amply large and are provided with oil rings and water cooled chambers.

The steam expands in the stationary nozzles and drives the rotary element on a single row of buckets. The pressure of air is maintained by means of a constant pressure regulator, which acts directly on the steam, being adjusted for any given air pressure by a weight sliding on a lever arm. These turbo blowers have been highly satisfactory. At 140-lb. steam pressure, they have delivered 20,000 cu.ft. of air per min. through a 20-in. pipe with 36-in. pressure at the Venturi meter. Such apparatus must be given more care than is usually given to blast equipment for water gas sets.

The stack valve, up-and-down run valve, steam valve, secondary and primary blast gates are all handled by hydraulic valves. These hydraulic valves are controlled by a group of levers set together at a convenient place for the operator of the machine. The action of these valves is extremely smooth and satisfactory and has made the labor of operating the machines very light compared to the old fashioned manner of working.

During the period of blowing, the amount of secondary air required to make perfect combustion at the stack must constantly be increased, and to maintain this condition, an automatic device is made use of. This device consists of a small gas holder, which is filled

during the blow by the air pressure from the main blast line. As this little holder gradually rises, it automatically increases the flow of air to the carburetor and, by means of simple adjustments, the right amount of air is admitted during each minute of the run to secure complete combustion of the carbon monoxide generated.

Venturi meters are used for measuring the flow of air to the generators during the blow. The pressure indication of the meters is transmitted to a water column on the gageboard of the machine, this column having a graduated scale, from which may be read the amount of air in cubic feet passing the fire per minute.

Venturi meters are also used for measuring the up-steam and down-steam used during the gas making period. The meters are equipped with indicating dials, which show directly the number of pounds of steam entering the fire per minute of run.

FIG. 9. GENERATOR HOUSE OPERATING FLOOR

To indicate the temperature at the top and bottom of the superheater, Bristol indicating pyrometers were originally installed. During the last year, on account of the poor oil and fuel which were obtainable, much more careful operation of the machines was demanded and Thwing recording pyrometers were installed, which made a record of the temperature at three points, namely: the middle of the carburetor and top and bottom of the superheater. These instruments are installed in a little dust-proof room just off the operating floor and have given great satisfaction.

A gageboard is provided for the use of the operator of the machines, located in a convenient place for his observation. On this board are placed gages showing the pressure of the blast air and, during the run, of the pressure under the grate and the pressure leaving the

*Read before the American Institute of Chemical Engineers, Cambridge, Mass., June 20, 1919. Part I published in CHEM. & MET. ENGG., Vol. 21, No. 1, July 1, 1919, p. 34.

FIG. 10. TAR EXTRACTOR AND WASHER

machine. On the upper part of the gageboard is a gas maker's clock with a very conspicuous second hand, two dials, indicating, respectively, the amount of steam used on up-runs and down-runs, and a graduated gage glass for indicating the amount of air passing through the generator during the blow and a gage indicating the pressure of oil in the line going to the sprays. Back of the gageboard and in a convenient location is the battery of levers which control the operation of the hydraulic valves used in handling the various parts of the machine. There is also a meter for measuring the amount of oil admitted to the machine during each run. On the wall directly back of this bank of valves is an indicating pyrometer. It will be seen that great care has been taken to make the work of the operator convenient and easy, and it is possible to secure a very high degree of efficiency by such an arrangement.

The general design of these water gas machines does not depart from the standard American Lowe carburated water gas plant as developed by the United Gas Improvement Co. and embodies those details of construction and operation which have proved themselves by many years of successful operation.

Coal or coke for use in the generators is delivered by means of chutes from the outside bins to trucks or buggies on the operating floor. These buggies hold about 3600 lb. of coal and are drawn over scales for weighing before discharging their contents into the generators.

The washer tar batter is a recent development of the United Gas Improvement Co. and it takes the place of the seal pot and tray scrubbers usually employed. It is set upon the operating floor at the side of the extended superheater with a short connector from it and consists of a steel plate shell with an internal divided flow dip pipe. Water, tar and foreign matter are removed by impingement on baffles as the gas passes through. In addition to its scrubbing action, the back pressure, during the gas-making period, is less with this type of apparatus, owing to the greatly increased perimeter of the 4-way pipe over that of a single dip pipe. This apparatus has given no trouble and has been uniformly successful in its operation.

Gas Main and Relief Holder—Leaving the seal pots, the gas enters a 36-in. outside overhead main, which

carries the gas to the relief holder. This main is made of riveted steel pipe and is supported on steel trusses. The relief holder is of 500,000 cu.ft. capacity, in two lifts, in a steel tank, and is of the Bartlett Hayward standard style of construction.

Condensers—Gas is drawn by means of exhausters from the relief holder through a battery of two outdoor water tube condensers. These condensers are rectangular in form and have seven compartments, gas passing from one compartment to the next and being made to impinge upon the tubes by means of baffle plates. These condensers are constructed of cast iron, which permits the use of salt water from the bay. The temperature of the gas leaving the condensers is regulated by means of a Tagliabue control apparatus acting on the main water lines. Two pumps are provided for handling the salt water to the condensers, one of which is a spare. Both are centrifugal pumps, one being motor driven and the other operated by a steam turbine. From each compartment of the condensers a tar drain connects to a common tar main, which delivers tar and condensed water to the general drip system of the water gas plant.

Exhausters and Pumps—Two No. 10 Roots gas exhausters were brought from the South Station and set up in a new engine room. These exhausters have been driven at the rate of 400,000 cu.ft. of gas per hr. each, which is equal to the largest demand which has yet been placed upon the plant. During the past year, considerable trouble was experienced with the engines, owing to there being a rigid coupling between the exhauster and the engine, and this rigid coupling was replaced by rope couplings, which have given great satisfaction.

In the pump pit in the north end of the engine room are located seven Simplex pumps, which serve the general yard drips, circulating water to the submersion washer, washer tar batters, tar tanks, and oil supply from the oil tanks to the water gas machines.

Each pump is equipped with a constant pressure regulator and the oil pumps have, in addition, a by-pass relief valve, so that a very uniform pressure is maintained in the oil line.

Tar Extractor and Submersion Washer—After leaving the exhauster, the gas passes underground to the P. & A. house, where it first enters a submersion wash-

FIG. 11. WATER GAS PURIFIERS, SHOWING COVERS, BELT CONVEYOR AND CRANE

er supplied by the Western Gas Construction Co. This washer operates at a differential of about 2½-in. at full load and is fed with a small stream of warm water from the tar separators. This washer is built in two sections, one above the other. (Fig. 10.)

Following the submersion washer is a P. & A. tar extractor, designed and built particularly for water gas tar extraction by the Gas Machinery Co., Cleveland, Ohio. This extractor consists of a steel plate shell, housing a series of concentric slotted metal drums. This extractor operates at a differential of about 7-in.

FIG. 12. DIAGRAM OF TAR SEPARATING SYSTEM

under full load. The capacity of the tar extractor plant is in the neighborhood of 10,000,000 cu. ft. per day and the plant has been satisfactory in every respect.

Purifiers—From the tar extraction apparatus, a 30-in. underground cast iron main runs to the purifying house—a distance of approximately 700 ft. There are four purifiers, 45 ft. by 25 ft. by 12 ft. (Fig. 11.) The four boxes are set in a line, connected on long sides by means of common partitions. The sides and bottoms of the boxes are constructed entirely of steel with riveted joints. The inlet and outlet connections are 24 in. in diameter. Each box is provided with two layers of tray supporting beams and two layers of oxide have been used, although provision was made for four tiers, if desired. The valve connections are so designed as to permit of passing the gas through the oxide from top to bottom or from bottom to top and also the boxes may be operated in forward or backward rotation.

To the bottom of each purifier are attached six oxide dumps, 20 in. in diameter, provided with self-sealing lids. The covers are of steel and are trunk shaped, reinforced by means of steel lattice girders located on the inside of the covers. The sides of the covers are formed of a heavy curved angle, which engages with an asbestos lute carried on the frame of the box. The covers are provided with holding-down clamps spaced about 40 in., center to center, designed to withstand a pressure of 36 in. of gas and any additional load due to tightness of the clamps.

The purifiers are supported upon steel beams, girders and "H" columns. For handling the purifier covers a traveling crane was provided operated by man hoists. In filling boxes, oxide is dumped from wagons or wheel-

barrows into a bucket conveyor, which transfers the oxide to the top of the building, dumping into a belt conveyor, located at the bottom chord of roof truss and extending the entire length of the building. The conveyor was provided with a tripper for discharging the oxide to either of the four sets of filling spouts located above the boxes. This apparatus is motor driven.

Meters—From the purifying house, the gas passes underground to the meter house. When the meter house was built, space was provided for four meters, only one being originally installed for coal gas. At the time of constructing the water gas plant, a 12-ft. and a 14-ft. Tufts meter with Hinman drums were removed from the South Station and re-erected in the present meter house, the gas passing through these two meters in parallel, thence passing to the mixing mains, where the coal gas and water gas were brought together and sent to the distribution holders.

Storage Tanks—One 500,000-gal. steel plate tank was removed from the South Station and two others were erected on concrete foundations over piling. Two tanks have been used for the storage of water gas oil and one for water gas tar. These tanks give a gravity flow to the oil and tar pumps. Oil is received by barges from an oil depot on the other side of the bay and is pumped from the barges into the oil tank.

Tar Separators—The experience with tar separators has been somewhat unusual and has many points of interest. As originally laid out, the tar separating plant consisted of a reinforced concrete settling tank, 20 ft. by 15 ft. by 8 ft. deep, and two separating tanks, 60 ft. by 25 ft. by 7 ft. deep, followed by a cooling tank 52 ft. square and carrying about 6 ft. depth of liquor, the liquor finally passing through two coke filters and discharging into the bay. The tar and water from the generator house, after passing through the seal pots on the machines, first entered the settling tank and then passed into a common header, which also received the tar and condensation from the other parts of the water gas plant. It then passed in parallel through the two separating tanks, thence to the cooling tank and from here the water recirculated through the various pieces of apparatus. This apparatus was never very satisfactory and did not give complete separation of tar from water. In addition, settling took place, so

FIG. 13. GAS PRODUCERS AND ACCESSORIES

that the tanks cracked and leaked. In the summer of 1918, these tanks were waterproofed by means of a combination tar paper, pitch and sheet metal covering with a layer of concreting to hold and protect the waterproofing. This rendered the tanks waterproof and any further settlement is not feared. After studying the behavior of our tar and water emulsions, the following system was finally adopted: The first settling tank was abandoned, as apparently it served no useful purpose. The liquor from the wash boxes in the generator house was caused to pass into the first or right hand settling tank and double the original number of dams and baffles were provided, so that twice the separating effect was secured. The depth of liquor in the tanks was also increased about 15 per cent. The overflow from this tank, instead of going to the cooling pond, returned to the left hand or second separating tank.

The effluent from the tar extracting apparatus, condenser, exhaustor house drips, etc., passed into a demulsifying chamber located at the entrance end of the second or left-hand separator, where it passed over a series of steam-heated pipe coils, thence discharging into the separator, where it mingled with the liquor coming from separating tank No. 1. The number of baffles and dams was also doubled in this second separator and the overflow from it went to the cooling tank and thence through the coke filters to the bay. The water for circulation through the wash box, etc., instead of being taken from the cooling tank, was taken from the end or separating tank No. 1. It will readily be seen that several improvements have been made. The length of travel has been doubled by placing the separating tanks in series instead of in parallel and, in addition to this, the separating effect in each tank has been doubled by doubling the number of baffles. Furthermore, inasmuch as the circulating water is now taken from No. 1 separating tank, the flow through the second separating tank is greatly diminished, as the volume of material to be handled is very much less than if the circulating water was taken from the outlet end of the whole system. The system as finally adopted has worked with great satisfaction, although, due to the forced employment of an inferior grade of oil during the past year, it has not been possible to secure water gas tar having a low moisture content, but the separation of tar from the circulating water is practically perfect.

The accompanying illustration (Fig. 12) shows the general layout of this apparatus. We are now using the first settling tank for storage of drip oil, etc., which we use in our boilers. The black solid lines show the flow of tar and water as now operated. The double lines

FIG. 14. HOT GAS MECHANICAL GENERATOR

show the original connections, which are not now in use. As is very well known, during the early part of the year 1918 there was a great shortage and demand for all products of ammonia. This fact was well recognized by the engineers of the gas company and influenced them in deciding upon by-product recovery producers. After the order had been given for the producers and before the details of the cleaning and ammonia extraction plant were worked out, this demand ceased and the original plans were not carried out. The plant as it is now, therefore, consists of by-product producers which may be operated either with or without by-product recovery and a set of apparatus for cleaning and cooling the gas, which has been considerably modified and simplified from the original design, although the plant could readily be converted for ammonia recovery, should it so be desired at any time in the future.

Gas Producers—The gas producers are five in number and were built by the Wellman-Seaver-Morgan Co. They are designed to produce gas from bituminous coal

either with or without recovery of ammonia; or to produce gas from coke. Generally speaking, these producers are a modified form of the standard Hughes producer, the principal difference being in the maximum depth of fuel possible and the massive size of the machinery column, stirring mechanism, etc. (Fig. 13.)

In a casual observation, an engineer familiar with gas producers is immediately struck by the great height of this apparatus. The distance from the floor line to the top of the producer is 20 ft. 9 in.: from the top of the air inlet or tuyere in the lower part of the producer to the under side of the top, 10 ft., which would allow a fuel bed of 8 or 9 ft. in depth, including the ash and clinker zone. The inside diameter of the steel shell of the producer is 11 ft. 6 in. and there is a 9-in. fire-brick lining, which reduces the diameter to 10 feet. (Fig. 14.)

When operating for plain gas production, the producer shell is rotated at a speed of one revolution in ten minutes. If it is desired to operate for by-product recovery, this speed will be cut in half. The ash pan is free to revolve independently of the shell but, owing to the presence of ashes in the pan, it revolves with the shell, due to the binding action of the wet ashes. In order to keep the ash bed and lowest zone of the producer in a free condition, it is arranged to have this ash pan take an intermittent retrograde movement with reference to the producer shell. This is secured

by means of two trippers set at 180 deg. apart, which, by striking a stop, cause the ash pan to rotate for a few inches in a direction opposite to the rotation of the producer shell.

Coal is fed to the producer from an overhead coal bin by means of a gas-tight measuring feeder, which is operated by the motor driving the rest of the producer mechanism and can be adjusted through a wide range of speed in feeding. For stirring the fuel bed, a long poker is provided, which is dragged through the fire in a direction approximately at right angles to the direction of rotation. On No. 1 producer there are two pokers—a long and a short—which would be used in all the producers should they be operated for by-product recovery with a deep fuel bed. When using a deep fuel bed, the long poker stirs the zone just above the ashes and the short poker penetrates about 2 ft. below the top of the coal. The other producers are equipped with a single poker only, but the poker shaft is arranged to take the second short poker at any time desired in the future. (Fig. 15.)

These producers are blown with air saturated with steam, the air being furnished by Coppus steam turbine blowers at pressures running from 8 in. to 24 in., depending on the depth of fuel, depth of ash zone and other conditions. The exhaust steam from these blowers goes into the blast air and additional steam is also admitted under careful control, so that the temperature

FIG. 15. BY-PRODUCT MECHANICAL GAS GENERATOR

FIG. 16. BARBOTAGE AND WASHER COOLER

of the blast air is an indication of the amount of steam being used. This temperature may be 140 to 150 deg. F. more or less, depending upon the conditions, and this represents something like 1.2 lb. of steam per lb. of coal gasified.

Air is admitted to the center of the producer through a double headed tuyere, and also by means of a hollow spider the air is admitted at the sides of the producer in order to obtain an even distribution of air. The producer house is arranged for six producers, and should the plant operate for ammonia recovery, it is probable that six would be needed, five only being installed at the present time, which it is felt is ample for the heating of the forty coke ovens operating on 15-hr. coking time, running four producers with one idle for cleaning or repairs.

Roughly speaking, about 100 tons of bituminous coal of good quality must be gasified to heat the battery when in full operation. If ammonia recovery is practiced, probably not over 20 tons of coal will be gasified per producer per day. On the other hand, when operating with a shallow fuel bed without recovery of by-products, it is believed that three producers are entirely sufficient, inasmuch as 35 tons of coal have been successfully gasified in one producer in 24 hours.

In the first weeks of operation it was found that the heating value of the gas varied from 135 to 175 B.t.u., depending on depth of fuel, amount of steam, blast pressure, etc.

The oven battery is so designed that all or any part of the battery may be heated with producer gas, and a great deal of experimental work has been done in determining the range and capacity of the different parts of the producer gas plant by varying the number of ovens heated from one producer and also varying the coking time; thus demonstrating the extremely flexible arrangement of the combined producer gas and run of oven gas system for heating the coke ovens.

Gas Treatment—The preparation of the gas for use in the coke ovens requires removal of dust, pitch, tar and a large portion of the moisture and heat, the maximum desirable temperature at the outlet of the fuel gas holder being in the neighborhood of 100 deg. F. This problem was given to the Steere Engineering Co. of Detroit, who designed, built and installed all of the

cleaning apparatus, acting also as engineers and erectors on the producer gas plant as a whole. The major portion of the apparatus was designed in line with the standard practice of the Steere Engineering Co. for clean producer gas plants, several improved and new features being introduced.

Dust Catcher—The gas leaving the producer has a temperature of 1100 to 1300 deg. F. and is laden with coal dust, soot and pitch. It first enters a dust catcher (one of which is provided for each producer), where a sharp and sudden change in the direction of the gas is caused, precipitating the dust to the bottom of the dust catcher. To accelerate this action, a heavy spray of hot water enters the dust catcher and strikes the inner cone, dropping thence to the bottom and washing out dust, etc., into a concrete separator.

Each dust catcher discharges its gas into a common collection main running the entire length of the battery of producers. In this main the gas is also heavily sprayed with hot water, the overflow running to the concrete decanter or separator. The gas issues from the collection main at a temperature of 165 to 175 deg. F.

Barbotage—From the collection main the gas enters the barbotage, which is a long rectangular steel box open at the bottom and sealed in the water in the decanter. (Fig. 16.) Inside of this box is another steel box with swinging sides, having serrated edges, the serrations dipping into the water. The gas comes into the inner box and is wire drawn over the surface of the water through the serrations. These swinging sides are balanced by weights and the differential through this apparatus remains the same when changes in the amount of gas passing occur, as, when the gas flow increases, the balanced vanes are blown outward, thereby opening a larger space for the gas to pass through in the serrations but maintaining the same relative action. On the other hand, if the gas flow diminishes, the swinging vanes come inward, decreasing the opening in the V-shaped serrations and again adjusting the wire-drawn effect to accommodate the amount of gas passing.

FIG. 17. WASHER COOLER, TAR HEATER, SEPARATOR AND DECANter

FIG. 18. IONIZER

The barbotage is equipped with sprays for use when necessary. At times dust accumulates on the surface of the water and interferes with the washing effect, and these sprays will drive this accumulation of dust down to the bottom of the decanter.

Washer Cooler—The gas has now been freed from excessive heat, dust and a large portion of the soot. Very little pitch has been removed, and this, together

with the light and heavy tar and finely divided free carbon and dust, is still present. To remove a portion of these impurities and to prepare the gas for further treatment, the gas passes through a washer cooler, which is an upright steel shell filled with wooden grids, the gas passing up through the grids, which are heavily sprayed with cold water. (Fig. 17.) This is an exceedingly efficient method of cooling gas and also of removing impurities. The gas leaves the washer cooler at a temperature of about 105 deg. The water enters at about 95 deg. and is brought to a high temperature in passing through the washer cooler, which discharges into the general decanter which extends beneath all the cleaning apparatus.

Tar Batter and Ionizer—For the removal of finely divided pitch globules, heavy and light tars and very fine dust, a combination of centrifugal batting and electrical treatment is used. The gas first enters the tar batter, which is an apparatus something like an enclosed fan, which revolves at 1700 r.p.m. and is supplied with a spray of warm water. The centrifugal action on the gas serves to throw off all the large globules of pitch and heavy tar and the tar and pitch which is not thrown out and washed away by the spray is disintegrated into an extremely fine state. It then passes into the ionizer, which consists of a cylindrical shell containing a series of parallel tubes, each tube having at approximately its center a wire carrying electrical charge of alternating current with a potential of about 17,000 volts. Passing through this electrically charged atmosphere, the finely divided globules of tar and pitch are coagulated and coalesced and driven against the walls of the tubes running down into the bottom of the apparatus and going thence to the decanter. The jacket temperature of the ionizer is maintained at about 140 deg. F., which serves to keep the tar and pitch reasonably fluid, so that it will not build up on the tubes. The temperature of the gas passing through the ionizer is maintained at about 100 deg. F.

FIG. 19. DIAGRAM OF TAR SEPARATING PROCESS

(Fig. 18.) After leaving the ionizer, the gas goes to two exhausters built by the Connersville Blower Co. and driven by vertical steam engines. These exhausters are automatically governed to maintain a very slight pressure just above the fire in the producers and force the gas through the rest of the cleaning apparatus over into the fuel gas holder. The temperature of the gas leaving the exhausters is about 105 deg. F.

Tar Separator—In the natural course of operating the plant, there are times when various portions of the plant must be by-passed for various reasons, which would permit some tar and dust to be present when leaving the exhausters. To take care of such emergency conditions or overloads, a tar separator was installed, which consists of a rectangular steel box, containing three sets of slotted plates with a backing plate behind each slot. The gas in passing through these knife edge slots is drawn into an exceedingly thin ribbon with high velocity, which, striking against the backing plate, is sharply deflected. This drawing action, combined with the sudden change of direction and further assisted by a spray of cold water which passes down the length of the slot, serves to remove traces of impurities which may be present at this point. After leaving the tar separator, the gas passes through a vertical pipe, where it rises for several feet, meeting a heavy spray of cold water, and thence passes directly to the fuel gas holder, which serves as a relief valve during the periods of reversal of the gas from one side of the coke oven to the other. All the seals on the cleaning apparatus discharge into a concrete decanter, which has several different compartments. In this decanter the tar and pitch separate from the water and suitable means are provided for the disposal of these materials. (Fig. 19.)

A set of centrifugal pumps is provided for handling the various circulations of hot, cold and warm water utilized. A suction pipe at the extreme end of the decanter takes the hot water to a pump, which sprays it in a cooling pond, where it is sufficiently cooled for reuse. The cold water from the cooling pond is drawn back and pumped over the washer cooler, tar separator and other places where a spray of cold water may be necessary. Hot water is secured by a suction line placed directly beneath the washer cooler, and hot water is used on the dust catcher, collection main and barbotage or other places where it may be temporarily desired.

The final results of this plant have not yet been definitely determined, but it has already demonstrated its ability to make absolutely clean gas within certain definite ranges, although the exact capacity of the plant as a whole has not been entirely demonstrated.

Minerals Relief Commission

The following procedure has been adopted in connection with claims arising under the Act of March 2, 1919, known as the Minerals Relief Act:

After the findings of the Minerals Relief Commission have been made, twenty days will be allowed claimant to file typewritten or printed brief based upon the record already made, making such comment on the Commission's findings as may be desired. At the end of 20 days the case will be finally submitted to the Secretary of the Interior. No new facts will be considered, those which have been submitted to the Commission only being given consideration. No oral argument will be heard.

Government Ownership of Water Power in Relation to Electrochemical Industry*

By F. A. J. FITZGERALD

THE examination of government ownership of hydro-electric developments in relation to electrochemical industry should cover a study of the effect of government ownership on the hydro-electric system considered as a productive industry in itself; the effect of this ownership on electrochemical industries which depend for their supply of electricity on the hydro-electric system; the effect of this ownership on the small user of electricity, such as the householder, and the nation at large.

Now, as regards the last consideration, it is not necessary to do more here than emphasize the fact that electrochemistry has become of such vast importance to the well-being of all the people that anything which affects its development adversely is bound to react on the nation as a whole. This was well brought out in a resolution of the board of directors recommended to and adopted by the American Electrochemical Society at its thirty-first general meeting in Detroit, May 3, 1917.¹ This report also emphasized the self-evident point that for the successful development of electrochemical industry an abundant supply of cheap electric energy is necessary. Therefore, in this report we may confine ourselves simply to a consideration of the effect of government ownership of hydro-electric systems considered as industrial undertakings.

ARGUMENTS BASED ON THEORY

Arguments in favor of government ownership of hydro-electric systems are based usually on theoretical grounds, because, with an exception to be noted later, we have no good example of this specific kind of government ownership from which to draw conclusions. It is pointed out that the chief item in the cost of water-power developments is the interest on the investment and that governments can accordingly construct and operate such systems much more cheaply than can private companies. The government can borrow money at a much lower rate than private individuals can, and, since it is not in the business for the sake of profit, it will establish suitable sinking funds to pay off all the investment, and eventually every one—the householder, the factory needing mechanical power, the railways, electrochemical industries—will get electric energy at an actual cost which is far below anything which we can now conceive. Furthermore, it is argued that, on account of governments being in a position to develop water powers much more cheaply than private individuals can, many of these which must inevitably go to waste if left to private initiative would be utilized, to the great benefit of the people.

In reply to these theoretical arguments certain examples of government ownership may be cited and must be given considerable weight, because they are examples of government ownership in actual practice and not merely deductive arguments based on theoretical considerations.

*An address delivered at the meeting of the American Electrochemical Society, New York City, April 3, 1919.

¹Transactions, Am. Electrochemical Soc. (1917), XXXI, 16 et seq.

A classical example of government ownership is found in the case of the Chemin de fer de l'Ouest in France, which is well known to compare most unfavorably with the privately owned railways.

Perhaps, however, one of the best examples of the failure of government ownership is found in the British telegraph system. This was originally a private enterprise, but was taken over by the government in 1870. For the first two years, that is, during 1870 and 1871, the government made a small profit after paying interest on the debentures issued for the purchase of the system, but since that time the system has been run at a loss. In 1914 the Rt. Hon. Sir Charles Hobhouse, the Postmaster General, in a speech in the House of Commons, declared that in the last 40 years the British Government's expenditures on the telegraph system, not including interest on annual losses, or any provision for amortization, were in excess of receipts by \$110,000,000, while if the interest on losses and amortization were charged the loss would be \$200,000,000. The average annual operating loss for the years 1908 to 1915, inclusive, amounted to over \$2,000,000, while for the same period the average loss, including interest and new money expended, amounted to more than \$5,500,000. In 1916 a committee appointed by the government to investigate the possibility of saving money in government expenditures stated in regard to the telegraph system:

"The history of the telegraphs is most unsatisfactory. They were taken over in 1870 at a cost (including capital expenditures on extensions) of £10,129,687 in the anticipation that they would yield a profit to the State. After the second year of Post Office management the profit failed to cover interest on the capital outlay. Year by year the financial position has grown worse and worse. In recent years the loss upon working has not been less than £1,000,000 a year, and this loss includes nothing for interest due to the State upon the aggregate losses of previous years."

MANITOBA'S EXPERIENCE WITH TELEPHONES

Another example of government ownership that is, perhaps, more interesting than the British telegraph system because it is found on this continent and because it is an undertaking initiated much more recently is the telephone system of the Province of Manitoba, Canada. It has been the subject of a most valuable and interesting study by Prof. James Mavor of the University of Toronto, published in book form by Moffat, Yard & Co. of New York and the MacLean Publishing Co. of Toronto under the title "Government Telephones; The Experience of Manitoba, Canada."

The Manitoba government took over the telephones in 1907 and Professor Mavor's study covers the history of this experiment from that time till 1915. It would take too much space to review the book here, but we may quote one of the final conclusions amply borne out by Professor Mavor's masterly study:

"The entire history of the government telephone enterprise in Manitoba affords evidence of the most positive character against government ownership. Practically all of the defects which have emerged elsewhere in the management of industries by State officials have made their appearance in the case of the Manitoba telephones. The management has been ineconomical, the enterprise has been handicapped by political intrigue, the finances, mingled as they have been with the general finances of the Province, have been unsoundly

administered from the beginning, and the obligations of the public have been enormously increased without adequate compensatory advantages.

"It is possible that only by repeated and costly failures such as the Manitoba government telephones will the public realize that the proper function of government is not the conduct of industries, but the impartial inspection of them under intelligent laws adapted to the character and conditions of the community and the country."

These are typical examples where we might expect to find confirmation of the arguments advanced by advocates of government ownership, but this is lacking.

HYDRO-ELECTRIC COMMISSION OF ONTARIO

As regards the government ownership of water powers we have fortunately one large-scale experiment in the case of the Hydro-Electric Commission of Ontario. This system is composed of several different parts throughout the Province of Ontario, Canada, and up to Oct. 31, 1917, involved a total capital expenditure of \$36,976,900.99.²

The first important agitation looking toward government ownership of water powers in Ontario apparently began in 1900, when the Board of Trade of the City of Toronto applied to the Legislature for power to undertake the development and transmission of electricity from Niagara Falls.³ This application was not favorably received, but the agitation in favor of public ownership continued and finally in January, 1906, the government appointed the Hydro-Electric Commission of Ontario. This Commission was given very great power, as may be seen from a study of the legislation which has been enacted and which may be found in a bluebook entitled "The Power Commission Act and the Hydro-Electric Railway Act," etc., published by A. T. Wilgress, Toronto, 1917. This bluebook will in future be referred to as "The Power Commission Act."

Originally the Hydro-Electric Commission was supposed to engage merely in the transmission and distribution of electric current; but it soon determined to undertake the generation of electricity on its own account, to construct its own hydro-electric plants, to compete with private companies, and there can be little doubt that it intends, if possible, to monopolize the hydro-electric systems of Ontario, judging from the statement of its chairman, Sir Adam Beck.⁴

It would, of course, be impossible in this report to make anything approaching an adequate review of the results of the Hydro-Electric Commission's activities, but reference should be made to an extremely interesting study of these in a pamphlet entitled "Public Ownership and the Hydro-Electric Commission of Ontario," published by the MacLean Publishing Co., Ltd., Toronto, 1917. This contains a reprint of a series of articles by Professor James Mavor of the University of Toronto as well as certain other articles which appeared in the *Financial Post* of Canada. Future references to this will be abbreviated to "Public Ownership."

TWELVE OBJECTIONS TO GOVERNMENT OWNERSHIP

In his examination of the Hydro-Electric Commission Professor Mavor considers twelve objections to gov-

²"Government Telephones," by James Mavor, pp. 163-164.

³Hearings before the Committee on Water Powers of the House of Representatives. Sixty-fifth Congress, Part 3, p. 725 et seq.

⁴Ibid., p. 702.

⁵Hearings before the Committee on Water Power.

ernment ownership and illustrates these from the history of the Ontario scheme. These objections may be briefly set forth as follows:

1. Increase in political power is one of the main motives in public ownership.

2. The conduct of industrial enterprises by government officials is not subject to inspection by impartial authorities.

3. The management of publicly owned enterprises is ineconomical.

4. In entering into industrial undertakings the government is apt to minimize the risks involved and to underestimate the amount of capital required.

5. Government officials are reluctant to provide for the continuity of the enterprise by setting aside adequate depreciation and reserve funds.

6. In governmental activities of this character there is a tendency to promote the illusion that profits inhere in industrial enterprises and to disregard the fact that, save in rare cases of adventitious profits, these are due to economy and skill in management.

7. The tendency to overman governmental enterprises of this character and the engagement of employees on political rather than technical grounds.

8. The tendency to fix the price of the governmental product at an arbitrary amount so as to induce the public to believe that the service is being rendered cheaply rather than at a rate determined by the technical conditions of the enterprise.

9. The tendency toward frequent crises in the management of the enterprise resulting from the fundamental unsoundness of the methods usually adopted.

10. The absence in governmental industrial enterprise of an experienced board of directors, its place being taken by a committee of politicians or the nominees of politicians.

11. A government preoccupied with industrial enterprises neglects its proper functions.

12. Government ownership tends to promote the illusion that politics and business are interchangeable terms.*

EFFECT OF GOVERNMENT OWNERSHIP ON ELECTRO-CHEMICAL INDUSTRY

It will be seen that this treatment of the subject of government ownership of power plants is a consideration thereof on the broad ground of public policy, but it may be well to look for a moment in more detail on the immediate effect on electrochemical industry.

The one great argument advanced by the advocates of government ownership is that of the low price of power. There can be no question that the prices charged for domestic use by the Hydro-Electric Commission are, at least in many cases, apparently much lower than could formerly be obtained. This apparently lower rate can be reached for various reasons. For example, the Hydro-Electric Commission does not pay taxes, as a private corporation must. Then by a peculiar application of the principle of "no discrimination" it is possible to charge an extremely small rate for domestic purposes. According to Sir Adam Beck: "The small user buys electricity at the same price as the large user. There is a standard rate in every community which applies whether you use 10 hp. or 10,000 hp. In the case of domestic users the small consumer buys it for less than the large consumer."[†]

When the actual rates charged domestic consumers are examined it is found that "no discrimination" means frequently that the consideration of the cost of the service is omitted. Thus on the Niagara Falls system it is found that the domestic rates for Niagara Falls, Toronto, Kitchener, Hamilton and London are the same, though the current is generated in Niagara Falls. Now, it is obvious that the cost of the current at a place like London, more than 100 miles from Niagara Falls, must be more than at Niagara Falls, where the current is generated, yet the price charged for it is the same. Then we have in Kitchener, about 80 miles distant, Hamilton 40 miles, Toronto 80 miles, the same price.[‡]

In view of such an interpretation of "no discrimination" it is not surprising that a movement is now on foot among the consumers to agitate for a "uniform rate," which means that all customers of the Hydro-Electric Commission shall pay the same rate irrespective of their distance from the place where the power is generated.

It is obvious that the cost of power to consumers in the government-owned hydro-electric system is largely governed by their voting power and under such conditions electrochemical industries are bound to suffer, since they will certainly have to bear more than their fair share of the actual cost. It therefore follows that government ownership, so far as electrochemical industries are concerned, is not desirable.

PRIVATE COMPANIES COMPETE SUCCESSFULLY WITH GOVERNMENT

Another point that should be noticed is that, in spite of the extremely favorable conditions, such as freedom from taxation, that the government-owned system enjoys, private companies are still able to compete successfully with the government enterprise.

No one will deny that there have been many reasons for complaining of the behavior of private companies, but the evils thus resulting can be remedied through government regulation based on the principle of seeing that justice is done to all; but when the government itself engages in business enterprises of this sort there is no hope of getting justice, and herein lies the greatest danger of the government ownership of water powers. This is admirably illustrated in the case of the Ontario Hydro-Electric Commission.

The Government of Ontario through the Commissioners of the Niagara Falls Victoria Park made a contract with the Electrical Development Co. of Ontario to rent water power to it and under Clause 16 of the agreement of Jan. 29, 1903, bound itself as follows:

"The Commissioners will not themselves engage in making use of the water to generate electric, pneumatic or other power excepting for the purposes of the Park."[§]

REMARKABLE LEGISLATION

This agreement, of course, stood in the way of the Hydro-Electric Commission when it undertook to generate power from the Niagara River in 1916. Accordingly the following remarkable legislation is recorded in the Ontario Niagara Development Act:

"The exercise of the powers which may be conferred by or under the authority of this act or of any of them shall not be deemed to be making use of the waters of the Niagara River to generate electric or pneumatic

*"Public Ownership," pp. 15-48.

†"Hearings before the Committee on Water Power," p. 714.

‡Tenth annual report of the Hydro-Electric Power Commission, Vol. II, p. 164 et seq.

§"Public Ownership," p. 7.

power within the meaning of any stipulation or condition contained in any agreement entered into by the Commissioners for the Queen Victoria Niagara Falls Park." (6 Geo. V., ch. 29, cl. 7.)¹⁰

Naturally enough, the Electrical Development Co. was disposed to fight the government's repudiation of its agreement and therefore attempted to have the legality of its original contract passed on by the courts. This, however, proved to be impossible because the Hydro-Electric Commission had procured legislation of this character:

"Without the consent of the Attorney-General, no action shall be brought against the Commission or against any member thereof for anything done or omitted in the exercise of his office." (6 Edw. VII, c. 15, s. 21.)¹¹

Since of the three men constituting the Hydro-Electric Commission one of them was the Attorney-General, it is not surprising that the fiat which would permit the testing of the legality of the Electrical Development Co.'s contract was refused.

The Hydro-Electric Commission also has extraordinary powers in regard to the making of regulations as to the design, construction, protection, operation, maintenance and inspection of all electrical apparatus whatsoever used in the Province of Ontario, may order compliance with these and may order power supply cut off pending such compliance.¹²

A very serious situation was created by the Hydro-Electric Commission's activities during the war, and electrochemical industries were the chief sufferers. In spite of the serious shortage of power the Commission made every endeavor to extend the use of electric power in directions which would give it political power, with the result that electrochemical industries of great importance, not only to the prosecution of the war but to normal activities, were seriously hampered by having their power supply cut off.

RECAPITULATION

Whatever effect, whether good or evil, government ownership of water powers has on electrochemical industry will be transmitted to the nation at large.

Arguments advanced by advocates of government ownership are generally *a priori* and not based on actual experience.

Examples of governmental activities in various fields which can be undertaken by private enterprise offer evidence strongly against public ownership in such cases.

An examination of the only adequate example of government ownership of a hydro-electric system shows that all the evils have developed that are associated with governmental activities in fields other than those for which governments are instituted among men and that the largest individual users of electric energy, the electrochemical industries, will be the most direct sufferers therefrom.

ADDITIONAL NOTE

Since the above was written some more interesting and important information in regard to the Ontario Hydro-Electric Commission has become available in the shape of the report of Messrs. Clarkson & Sons, chartered accountants, on the accounts of the Commission. The government promised to have this investigation made in 1916¹³, but the report was not apparently avail-

able to the public till March, 1918, and had evidently been kept from publication for a considerable time, as it only covers the period ended Oct. 31, 1917.

Apparently the report, in spite of its inadequate nature, is in accordance with what might be expected in a governmental enterprise of this kind. For example, the original hydro act provides in regard to payment on sinking fund account that "a municipal corporation . . . may be relieved by the Commission from payment of any sum on account of the sinking fund account for the first five years . . . the amounts . . . on sinking fund account shall be payable during the next ensuing thirty years."¹⁴

This has been interpreted as meaning that no municipality shall be charged any sinking fund for five years.¹⁵ This ingenious distortion of the meaning of the act permits municipalities to conceal an actual loss on their enterprise.

It also appears that the report covers only the Provincial accounts, leaving out the systems of the municipalities which are controlled by the Commission.¹⁶

One remarkable charge shown by the report is a sum of \$1,117,433.86 against the ratepayers of the Province, a large number of whom are in no way benefited by the Commission's enterprise. This money is for items such as "Investigations and reports on proposed municipal railways," "Demonstrations at exhibitions as to use of electricity on farms," "Engineering assistance and estimates to municipalities not under contract," etc.¹⁷

This charge should, of course, be against the municipalities included in the hydro combination or against such of these as were directly concerned; but had this been done the government's enterprise instead of showing the net surplus of \$174,919.31, which it is made to do, would show a net deficit of \$942,514.55.

Obviously this report shows that had the Commission kept "regular accounts" as required by the Act¹⁸ "the results of an audit would show, and this report should show, that the operations have been carried on at considerably less than cost."¹⁹

Thus as time goes on the evidence which accumulates confirms what has already been observed in a large-scale experiment on government ownership of hydro-electric systems. It is only too obvious that those most directly affected will be the largest users of electric power, the electrochemical industries, and, looking at the subject from the broader aspect of the general good, that any partial or transient benefit derived from this encroachment of government upon industrial fields will be greatly overbalanced by permanent evil.

Decay of Woodpulp

At the spring meeting of the Technical Association of the Pulp and Paper Industry, attention was called to the annual loss of wood and pulp through decay, which has assumed such proportions as to present a serious economic problem. A resolution was adopted requesting Congress to appropriate \$20,000 for the purpose of conducting investigations on the nature and habits of the fungi and bacteria causing the decay of pulp wood and woodpulp, so that methods could be devised for controlling and, if possible, preventing decay.

A New Governor for Close Pressure Regulation of Gas Exhausters and Boosters

THE pressure regulation of rotary exhausters and boosters has occupied the attention of engineers off and on for more than 50 years. The "off and on" feature of the proceeding is due not only to the circumstance that requirements for closeness of regulation have become more stringent, but also to the change from throttling regulation to cut-off regulation. In order that we may appreciate the great difference between the two types of regulation, a brief review of the underlying principles will be made.

If a rotary exhauster works between given limits of intake and discharge pressure, and if the limits are to be kept constant, the work done by the engine per revolution is also constant.

Now let, of two engines, one be regulated by a throttle governor, and one by a cut-off governor. (See Fig. 1, which represents the indicator cards of both

FIG. 1. INDICATOR CARDS, THROTTLE AND CUT-OFF GOVERNOR

engines.) Then in the throttling regulation, any increase in speed of the engine will, for a given position of the governor, result in greater throttling loss and in less work per revolution. If the engine tries to slow down it is speeded up, and if it tries to speed up, it is immediately slowed down to its original speed. Conditions are, therefore, inherently stable.

It is quite different with cut-off regulation. If the engine speeds up, the work per revolution remains practically constant, and no large force is brought into play to bring the speed back to normal, unless that force comes from the engine governor.

Small self-regulating forces are brought into action, whenever a change of speed occurs, on account of friction of live steam and of exhaust steam through valves, ports and pipes, and on account of friction of the gas through pipes, tar extractors and the like. However, these forces are very, very small, and cannot be depended upon, except when changes in gas volume, steam pressure or back pressure are exceedingly slow and gradual.

While this fact has been known for quite some time in the governing of air compressors, it had, apparently, not been realized to the same extent in the governing of rotary blowers. The probable reason for this lack of application of correct principles of governing is the very general use of throttling regulation in connection with rotary exhausters; and that type of regulation is

justified wherever the demand of the ammonia stills for exhaust steam exceeds the supply of exhaust steam coming from a high class steam engine with cut-off regulation. On the other hand, the requirements for closeness of regulation are very much closer in the governing of gas exhausters than they are in the case of air compressors. This statement is substantiated by the following facts: In air compressor practice, a pressure fluctuation of 5 lb. per sq.in. is not considered serious. If the air pressure be 85 lb. per sq.in., then 5 lb. is 5 per cent of the absolute pressure (85 plus 15 lb.). In gas exhausters, particularly in connection with by-product extraction, the pressure at the exhauster is to be kept constant within 5 mm. of water. Since atmospheric pressure roughly equals 10,000 mm. of water, the required closeness of regulation equals $5 \times 100 \div 10,000 = 0.05$ per cent. This means that in modern gas exhausters the regulation must be 100 times as close as it is in compressor practice.

Although it is very interesting to follow the development of exhauster governors in history, such study would lead altogether too far in the present article. For that reason, we will now describe the new pressure governor, calling attention, as we go, to the various features. The governor in question is made by the P. H. & F. M. Roots Co., of Connersville, Ind.

To be successful for close regulation, a pressure governor must instantly react upon the slightest change of pressure. Compliance with this requirement is much more essential in relay governing than in direct control governing, because the float is practically free from all vibratory forces so that the harmful effects of detention of the governor by friction appear with full measure. Even a slight amount of friction causes the pressure to vary rhythmically up and down over a considerable range. For that reason, sensitive pressure governors have always been made of the float type, and the Roots governor, shown in Fig. 2, is no exception to that rule. To avoid any and all solid friction, the governor is, for work on gas exhauster suction lines, buoyed up by means of an air chamber, and adjustment of suction is obtained by placing weights on the weight holder (4) below the tank. This arrangement necessitates an additional water seal in the center of the float, but the entire freedom from friction is worth the additional parts.

A very great difficulty with sensitive float governors is hunting, or surging. If the pressure departs from the normal value, the governor sets out to change the position of the valve gear. The adjustment continues not only to the point where the volume taken away by the exhauster equals the incoming volume, but beyond that point, because the pressure cannot be returned to the original value, unless the accumulated excess or deficiency of volume has been made up. When this end has been accomplished the governor is away out of the right position and the speed is away off. It takes a new, greater change of pressure in the opposite direction to bring the governor back to initial position, and the surges and vibrations become greater and greater. In the governor under consideration the difficulty is overcome by a temporary stability, which keeps the governor from following the influence of pressure too far.

To that end it is equipped with a stabilizing chamber which is partly filled with water. If the float tends to rise under the influence of less vacuum inside of it, the water in the stabilizing chamber is lifted, so that

the float becomes heavier and resists being carried too far. It tends to come back to the original position. But it may be that the float would not settle in the original position, because steam pressure, back pressure or discharge pressure may have changed.

To enable the float to find its correct final position, the stabilizing chamber is made leaky on purpose, the extent of the leak being determined by an adjustable valve. The adjusting screw is visible at 3. With

FIG. 2. ROOTS GOVERNOR

that valve wide open, the governor surges; with the valve dead shut, the governor does not maintain a constant pressure, but adjusts for different pressures in the gas suction line with different combinations of steam pressure, back pressure and discharge pressure. The best opening of the valve is easily found in practice.

This temporary stability results in very fine regulation. If a disturbance of equilibrium occurs, the suction pressure departs slightly from the normal value, but a few oscillations with gradually decreasing amplitude soon bring the pressure back to the original value. In actual operation, this feature of the governor is easily tested by depressing the float away from its correct position and then letting go of it quite suddenly, or else by suddenly opening the by-pass from the discharge to suction on the exhauster. In either case the governor takes hold of the situation almost instantly.

The motion of the float is communicated to a vertical pilot valve 1 by means of light rods with very small pin joints which approach frictionless knife edges in their action. The pilot valve is made heavy on purpose, and is suspended from a floating lever, one end of which rests on a float, while the other end floats on the compensating return, the purpose of which is described below. In that manner, lost motion is eliminated and the slightest motion of the float is immediately transmitted to the pilot valve. The latter is made with an

open-view discharge. Leaky pilot valves are a prolific source of trouble, because they require considerable travel of the governor before the pressure fluid acts upon the power cylinder. With closed discharge pipes, leaks are not discovered until the regulation becomes defective, and at that time almost every other part of the governing system is suspected, except the pilot valve. With an open discharge, a leak is plainly visible and is corrected before the regulation becomes defective. Too much emphasis can hardly be placed on this feature. In many relay governors, regulation gradually loses its precision due to increasing leakage of the pilot valve, and the engine or turbine operators are unable to locate the trouble, but if defective regulation is caused by a leaky pilot valve, the visible discharge shows it.

The compensating return of the pilot valve is a feature which is well known in governing practice. (See Trinks, "Governors, and the Governing of Prime Movers," Van Nostrand, 1919.)

Without such returning mechanism, the slightest displacement of the pilot valve causes the valve gear of the engine to be moved away continuously from its starting position, until the resulting speed change and pressure change moves the governor and displaces the pilot valve in the opposite direction. The governor surges or hunts, and never comes to rest, unless accidentally the valve gear is in correct position while the pilot valve is closed and when the governor is at rest.

To avoid this trouble, the compensating return was provided. Lever 2 is so connected to the valve gear that motion of the valve gear, induced by opening of the pilot valve, closes the latter. The valve gear cannot run away from the pilot valve, and all causes for hunting and surging are removed.

The closeness of regulation obtained with the Roots governor depends to a certain extent upon the power requirements of the engine valve gear. With releasing gear for Corliss or poppet valves, 3 mm. total fluctuation of suction pressure can be obtained, except during periods of excessively quick change in gas volume, steam pressure, back pressure or discharge pressure, when the pressure fluctuation may reach 10 to 15 mm. of water. With non-releasing valve gear, requiring power cylinders of great volume, the total pressure fluctuation will rise to 5 or 6 mm. of water, with peaks of 15 to 20 mm. for the first wave of excessively sudden disturbances.

The difference in closeness of regulation is caused by the greater requirements of pressure fluid in the power cylinder for adjusting non-releasing gears. If the pilot valve be made large, to admit oil or water in quick flow to the power cylinder, the frictional resistance of the pilot valve detains the governor. If the pilot valve be made small enough not to detain the governor, the flow of oil or water is insufficient to get quick action out of the power cylinder. To get the same closeness of regulation, both for non-releasing gear and for releasing gear, would require a much larger float for the former.

The Roots governor is made independently of exhauster contracts, and is furnished separately to improve the regulation of existing installations. Patents are pending, covering the principal features of the governing device. The best sizes of float, of buoyancy and stabilizing chambers, of leakage valve, of pilot valve, of pilot-valve weight and of sizes of ports are the final outcome of several years of close study and expensive experimental research.

Synopsis of Recent Chemical and Metallurgical Literature

Automatic Heating Furnaces. Figs. 1 and 2 show sections of an automatic heat-treating furnace described by A. F. MITCHELL, metallurgical engineer, ordnance department, U. S. Steel Corporation, in the January, 1919, issue of the *Blast Furnace and Steel Plant*. Shells are fed into and through this furnace automatically, being rotated during their forward travel; while in the furnace they are supported upon cast iron plungers operating through the bottom of the furnace and are not only kept separated, but are held several inches above the floor, thus insuring perfectly uniform heat in the minimum time. The furnace itself is quite substantially built, as is evident from Fig. 3. It is heated by means of side gas burners, whose flame impinges directly upon a mass of refractory material shown in the cross-section. Careful regulation of the gas composition is important so that the non-oxidizing atmosphere within the furnace may be under complete control and so that there will be no fuel loss due to imperfect combustion. Indirect heating by reverberation has eliminated heavy metal losses by surface oxidation, and in conjunction with an enlarged heating chamber has insured a much better distribution of heat. It has also been completely demonstrated that money spent in adequate insulation of roof and side walls is soon recovered by the largely increased fuel efficiency.

Solders for Aluminum.—Bureau of Standards circular No. 78 notes that aluminum is easily welded by oxy-gas processes, but ordinary soldering methods are somewhat difficult to apply. It is essential

FIG. 2. CROSS-SECTION. A—REFRACTORY MATERIAL

to prepare a clean, bright surface, which is then "tinned" by a high-melting solder with no flux. The Bureau recommends those compositions containing high percentages of zinc and aluminum selected from the suggested ranges given below:

Tin-zinc solders:		
Tin	...	Remainder
Zinc, per cent	...	15-50
Tin-zinc-aluminum solders		
Tin	...	Remainder
Zinc, per cent	...	8-15
Aluminum, per cent	...	5-12

A perfect joint is very difficult and can be had only at relatively high temperature. When the two pieces are properly "tinned," any ordinary soft solder will join them together. However, any solder compound examined is electro-negative to aluminum, and consequently the joint must be carefully and continuously protected from corrosion by paint or varnish, otherwise it will rapidly disintegrate and the pieces fall apart.

Working Results of a Rennerfelt Electric Steel Furnace.—In the course of the discussion of a paper on the "Prospects of the Electric Steel Furnace in Sweden," by Mr. OTTO FRICK, Mr. I. RENNERFELT and Chief Engineer H. VON ECKERMANN put in the figures as actual results, with a 14 ton Rennerfelt furnace (arc-type), at Ljusne in Sweden, during the five days, from Nov. 21 to 25, 1916. According to them, 12 charges were dealt with in the furnace in question, the average net time per charge being 6 hr. 39 min. The average input was 1.27 metric tons, of which 19.5 per cent consisted of common Swedish gray pig iron, 6.5 per cent of billet croppings, 64.5 per cent of bar croppings, and 9.5 per cent of scrap. The additions were in eleven of the charges, ferromanganese and ferro-silicon, plus, in five charges, small doses of aluminum,

FIG. 1. LONGITUDINAL SECTION OF SHELL HEATING FURNACE

some flux being added (Kilruna ore = 1.8 per cent average of the charge) in every case, plus a small quantity of lime in one case. The average output (including scrap left) was 1236 metric tons per charge; hence the loss was 2.44 per cent. The scrap left over represented 10.12 per cent of the weight of the ingots and direct castings produced. The consumption of electrodes was 5.1 kg. (11.22 lb.) per metric ton (2.205 lb.), and the energy consumed 1010 kw.-hr. per metric ton of steel (with 0.21 per cent carbon) produced. The work of the furnace was intermittent, hence the larger consumption of energy. With continuous working and producing steel

FIG. 3. AUTOMATIC HEATING FURNACE

with a carbon content of 1.20 per cent the chief engineer thought the average current consumption could be reduced to 800 kw.-hr. per ton of steel produced.—*Indian Engineering*, March 16, 1918, p. 149.

Volatilization of Gold.—Literature contains many efforts to determine the volatility of gold, and from this contradictory evidence Sir THOMAS K. ROSE, in a paper presented before the Institution of Mining and Metallurgy, Mar. 20, 1919, deduces the following factors affecting volatilization: Time, temperature, amount of exposed surface, composition of bullion, composition of atmosphere, and movement of atmosphere. Preliminary experiments to harmonize the pub-

lished information gave the most inconsistent results. The apparatus consisted of a quartz tube, gas heated, discharging into a condensing system. Microscopic examination of the condensed films showed them to consist of a multitude of spheres, of the order of 0.001 mm. diameter. Larger spheres sectioned, polished and etched gave polygonal crystalline grains, and no trace of concentric structure.

Considerable experimentation was necessary before the true blame for divergent experimental results was placed upon an inconstant atmosphere. When pure gold, or its alloys with silver or copper, are kept molten in a reducing or oxidizing atmosphere, the surface of the gold remains as a bright, motionless mirror. Under these circumstances the loss of gold is very small, being due to true volatilization. If there is a strong draught passing over the surface the loss by volatilization is naturally greater than in a still atmosphere, but is even then almost negligible at the ordinary temperatures of industrial furnaces.

Under all such conditions, however, gases are being absorbed by the metal. If the atmosphere above the gold now undergoes a change, say from an oxidizing to a reducing one, the quiet metal begins to effervesce due to the expulsion of certain of the occluded gases, possibly as new chemical combinations formed with the new atmospheric components.

Showers of globules of gold of all dimensions are thus thrown up, and the smaller sizes carried away by the current of gas. After a time, usually about 30 sec., if the reducing atmosphere is maintained, the action dies away, and the gold again becomes motionless and remains so until the reducing atmosphere is converted into an oxidizing one, when the same phenomena reappear. As molten metals occlude more hydrogen with increase of temperature, the greater losses observed at higher temperatures than at lower ones are readily explained. Other observed anomalies are due to the fact that pure gold does not occlude oxygen, hydrogen or nitrogen, while its alloys do.

It is evident that losses of really volatilized gold are extraordinarily small in industrial furnaces. Under constant atmospheric conditions, the author finds variations in weight between a loss of 0.052 to a gain of 0.017 per 1000. As a matter of fact the Royal Mint records a gross loss of between 0.2 to 0.25 per 1000, which is reduced to a net loss of 0.1 to 0.15 per 1000 after crediting the recovery from flue dust, ground crucibles and furnace bricks, ashes and sweepings. In less well conducted establishments the loss is of course much larger and may aggregate a half-million dollars per year. Under most rigid atmospheric conditions this can be enormously lessened, even granting the inevitable spiriting loss which occurs when metal melted under charcoal is poured through air.

Maxima Magnetic Susceptibilities.—At the meeting of the Interallied Chemical Confederation held in Paris in April, 1919, Prof. HENRY LOUIS read a paper on the treatment of low-grade iron ores by magnetic concentration. The following table is abstracted from this paper (*Chimie et Industrie*, May, 1919).

Ore	Locality	Susceptibility
Pure Soft Iron		400
Crystallized Pure Magnetite	Plemonst	3.12
Magnetite	Hay Tor, Devonshire	1.44
Magnetite	Lake Champlain, U. S.	0.151
Iron Sulphide	Artificial	0.064
Red Hematite		0.00037
Brown Hematite		0.00016

Recent Chemical and Metallurgical Patents

British Patents

Extracting Ammonia From Gases.—Ammonia is extracted from hot gases, for example from furnace gases or gas producers, by a solution of a salt such as calcium chloride, or zinc chloride, possessing the property of forming a double compound with ammonia, which is delivered as a shower or spray by one or more distributing devices provided with spraying nozzles into a vessel through which the gases are caused to rise.

The apparatus comprises a vessel *a*, having a gas inlet *e* and a gas outlet *h*, and provided at the top with a liquid distributing box *b* fitted with spraying nozzles *d*. The vessel *a* is without internal projections, and is formed with a sloping bottom, so that solid matter, for example calcium carbonate, formed when the gas treated contains carbon dioxide, is washed out of the vessel. The heated liquid containing the absorbed ammonia leaves the vessel by a pipe *c* and enters a box *m*, where the dust and solid matter taken up from the gases, and which float on the solution, are separated by a scraper or filter, for example by a vertical plate *i*, a lateral opening *M*, being provided in the side of the box for the removal of the separated matter. The liquid then passes through a settling tank *u* to a tank *v* where it

APPARATUS FOR EXTRACTING AMMONIA FROM GASES

is treated with milk of lime to liberate the ammonia, and the residual solution is returned by a pump *z* to the vessel *a*. The ammonia may be absorbed in water in a vessel *y*, or a plant for producing an acid or an acid anhydride may be provided, the ammonia and acid or acid anhydride being led into a vessel to form a salt, for example ammonium nitrate may be formed from the ammonia, water vapor and nitric anhydride made by the electric arc process.

When the hot gases contain tar in addition to carbon dioxide, a portion of the tar will be washed out of the gas and will mingle with the calcium carbonate, the mixture is removed in the separating box *m* and is burned for the recovery of the lime. The remainder of the tar passes off with the treated gas and may be separated by known means.

The hot solution before treatment to liberate the ammonia may be utilized for producing steam, or for heating water or other fluids.

In a modification, the hot gases are washed or scrubbed by a water spray in a separate vessel before

entering the vessel *a*. The washing may be carried out to such a degree that the whole of the tar is removed from the gas. (British Patent No. 121,754—1918. E. L. PEASE, Darlington, Durham. Feb. 26, 1918.)

Welding Different Metals to Steel or Iron.—Different metals are welded to steel or iron to form a composite ingot with a thin continuous sheet or strip of copper or other metal interposed between the welding surfaces, the sheet metal chosen being capable of alloying with a constituent of the metals to be welded. The metal to be welded, if of considerable thickness, may be in the form of thick sections alternating with thin sections. When a steel ingot is to be welded to another metal, the welding surfaces of the steel are first covered with tin or other easily fusible metal. (British Patent No. 122,365—1918. A. G. C. PITTEVIL, High Holborn, London. March 19, 1919.)

Refractory Bricks.—Separate portions of siliceous material, consisting chiefly of silica, one in relatively coarse powder and the other in a very finely divided condition, are mixed wet with animal or vegetable fiber, or both, to form a composition for molding. Both materials may be flint, chert stone, silica rock, quartz, sand, or stone rich in silica, calcined and the coarser is ground to 16 to 100 mesh. The fine material may or may not be calcined and will pass through a 250-mesh sieve. The fiber may be straw, chaff, peat, wool, hair or the like. The mixture of the two siliceous materials and fiber is mixed with water until the fiber is finely subdivided, molded, and the articles dried and fired at a temperature above 1500 deg. C. (British Patent No. 122,388—1918. C. H. SANKEY WILDCROFT, Chislehurst, Kent, and J. E. FOSTER, 48 Gilman St., Hanley, Stoke-on-Trent. March 26, 1919.)

Preparation of Dimethyl Sulphate.—Dimethyl sulphate is prepared by the reaction of sulphur trioxide on dimethyl ether in the presence of a solvent or diluent, preferably dimethyl sulphate itself. The sulphur trioxide used is preferably diluted with an indifferent gas; thus a current of air may be passed through hot fuming sulphuric acid and the resulting mixture of air and sulphur trioxide used, or the mixture of air, sulphur dioxide and sulphur trioxide resulting from the contact process of making sulphur trioxide may be used. The product of the reaction is treated either with ice or preferably with a reducing agent such as iron filings to destroy any sulphur trioxide present, and is purified by vacuum distillation. (British Patent No. 122,498—1918. W. N. HAWORTH and J. C. IRVINE, University, St. Andrews, Fifehire. March 26, 1919.)

Sulphurly Chloride.—A mixture of sulphur dioxide and chlorine in equimolecular proportions is passed over charcoal which acts as a catalyst to produce the combination with evolution of heat. The temperature should preferably be kept down to about 30 deg. C. (British Patent No. 122,516—1918. W. J. POPE, Holmesdale, Brooklands Avenue, Cambridge, March 26, 1919.)

Electrolytic Detinning Process.—An electrolyte for the recovery of tin from scrap and waste consists of a 7 to 10 per cent solution of caustic soda or potash in which is dissolved 1 per cent of stannous chloride. It is preferably heated to 180 deg. F. by a steam pipe. The scrap may first be washed in a caustic alkali or other solution to remove paper, etc., and placed in a perforated drum. (See British Patent No. 122,025—1918, for detailed description of this drum.) The drum is re-

moved to the electrolytic vat and rotated or oscillated. After electrolysis, the drum is washed in water and the liquid is concentrated for restoration to the electrolyte. Two vats are preferably used alternately for washing and evaporating. The drum is next removed to a solder-recovery plant, and the residual scrap is discharged into baling presses. (British Patent No. 122,618—1918. Sir H. GREVILLE LODGE, Sir Harry's Road, Edgbaston; M. L. LANCASTER, Arden House, Stechford; C. M. WALTER, Lichfield Road, Four Oaks, and J. JACKSON, 70 Oxford Road, Moseley, all in Birmingham. March 26, 1919.)

Book Reviews

METALLURGY OF LEAD. By H. O. Hofman, Professor of Metallurgy, Massachusetts Institute of Technology and Harvard University. First Edition, 1918; XIV + 664 pages, 705 illustrations, 153 tables. New York: McGraw-Hill Book Company, Inc.

Professor Hofman's earlier work on "The Metallurgy of Lead and the Desilverization of Base Bullion" has not been revised since 1899. Originally published in 1892, it at best now represents details of practice since largely changed in modernized and recently-built American plants. The character of the ores treated has gradually changed due to the constant exhaustion of older mines and discovery of new, while the universal adoption of blast roasting is not only one phase of the trend toward economy of man power but has profoundly affected the entire lead-plant economy, from a metallurgical viewpoint.

Consequently this new book devotes 330 pages to a chapter on Blast-Furnace Smelting and 170 more to Desilverization of Bullion, a total of 500. Short chapters on smelting in the ore hearth, and in the reverberatory, on lead smelting, and on the properties of lead, its ores, compounds and alloys, make up the remainder of the book, exclusive of a comprehensive index.

In style the book follows the author's monumental "General Metallurgy" published a few years ago. Professor Hofman has been reviewing the pyrometallurgy of lead for "The Mineral Industry" annually since 1892, and the abstracts of contemporary literature contained in great numbers give both these books an encyclopaedic value. However, the style is discontinuous and extremely difficult to read, giving the impression at times that the book is a compilation of dictated and card-indexed notes rather than that of a deliberate commentator on an intricate subject. Thus, there are illustrated and briefly described a large number of equilibrium diagrams of binary systems of compounds present in slags, mattes and other furnace products, but little indication how these studies may bear upon successful lead smelting. On the other hand a most excellent discussion of the chemistry of the blast-furnace is given on pages 339 to 345, which could readily have been expanded in many points and the connection between physicochemical theory and metallurgical practice pointed out at some length. Another contrast in style is unexpected of an author who uses the terms "smeltery," "wedge kiln," and puts a period after "per cent," yet uses through the running text chemical symbols of all metals and common compounds as well as such hybrids as "S-ides."

But enough of this side of the book. It is a monument to the extraordinary industry of the author, in that it contains a brief statement of all the scattered technical literature down to the time of going to press. Apparently the notable smelters and refineries in the United States were toured at intervals, and a lively correspondence maintained with their operators on technical matters, since the book abounds with observations culled from private notes and communications. Most notable is the excellent metallurgical and thermal balance sheet of blast-furnace practice at Ilerculaneum, Mo. Again, two very good general layouts

of complete and modern plants are given, one of the Bunker Hill and Sullivan smelter at Kellogg, Idaho, and a second design by Mr. H. V. Croll. The latter is accompanied by a somewhat detailed estimate of the cost of construction—in fact, the author should be praised for uniformly including in his estimates the *quantities* of materials used, in honorable contradistinction to others who apparently think that \$100 worth of brick are \$100 worth of brick!

It would be difficult to justify criticism as to the relative amount of space devoted to various divisions of the subject. Thus Professor Hofman passes by mechanical roasters with a brief mention, to devote a great deal of space to the almost extinct hand-reverberatory. However, in his very thorough discussion of blast-roasting (well worthy of the attention it is given) he returns to the subject of mechanical roasting in an adequate manner.

The size of the book under discussion and the limits accorded a reviewer forbid any more than casual mention of the most striking features of the major chapter, and entirely preclude detailed analysis and discussion of the few controversial points left by our somewhat standardized American practice. Enough has been said, however, to indicate the grounds of the reviewer's opinion that the book will be of tremendous value to the studious workers in lead metallurgy, primarily because of its minute review of literature and present plant practice—as a compilation it is wonderful! On the other hand it will be as difficult a book to teach, having the same failing as has his earlier "General Metallurgy"; that is, in his mass of detail of various plants, appliances and citations, there are too few cases where the author leads the young student to form correct opinions by pointing out the principles underlying a design, or discussing the relative advantages for the particular problem in hand—as a critique it is a disappointment! Perhaps it is as difficult to write in a manner instructive at once to the expert and the student as it is to purchase a single suit wearable on all occasions!

E. E. THUM.

Personal

MR. LESTER E. ARMSTRONG has accepted a position as advisory engineer with the Powdered Coal Engineering & Equipment Co., Chicago, Ill. Prior to his service in the Air Branch of the Army, Mr. Armstrong was associated with Babcock & Wilcox.

The duPont scholarship for the year 1919-20 at the College of the City of New York, Department of Chemistry, has been awarded to FELIX BRAUDE.

MR. A. G. GREENAMYER, formerly of the Pittsburgh Crucible Steel Co., Pittsburgh, Pa., has accepted the position of metallurgist with the Donner Steel Co.

DR. GEORGE ELLERY HALE, director of the Mount Wilson Observatory and foreign secretary of the National Academy of Sciences, who has been for the last ten years a correspondent of the Académie des Sciences, Institut de France, has received the unusual honor of election as Associé Étranger, taking the place of Adolph von Baeyer, declared vacant by the Academy. The Foreign Associates are limited to twelve, and the high distinction has been held by only two Americans—Simon Newcomb and Alexander Agassiz. The National Research Council, upon the presentation and acceptance of Dr. Hale's resignation as its chairman and the election of James R. Angell as his successor, created and bestowed in perpetuity upon Dr. Hale the title of honorary chairman in recognition of his services to the National Research Council and to science and research by indefatigable efforts that have contributed so largely to the organization of science for the assistance of the Government during the war, and the augmentation of the resources of the United States through the newly intensive cultivation of research in the reconstruction and peace periods that follow.

DR. ARTHUR W. HIXSON has been appointed associate professor of chemical engineering at Columbia University.

He entered on the duties of his new position July 1. Prof. Hixson was formerly associate professor of industrial chemistry and metallurgy at the University of Iowa, but for the last year he has been in the Ordnance Department at Washington.

MR. E. R. LEDERER, formerly superintendent of the Petroleum Refining Co. of Texas, has accepted a position with the Home Oil Refining Co. of Texas, Fort Worth, Tex., as general superintendent.

Leland Stanford, Jr., University has recently created a graduate department of mining and metallurgy which will be under the direction of THEODORE J. HOOVER. The chair of metallurgy will be held by JAMES M. HYDE.

MR. A. LUSSKIN is now research chemist with the International Oxygen Co., Newark, N. J. Mr. Lusskin was formerly on the chemical engineering staff of the Air Nitrates Corporation, Muscle Shoals, Ala.

DR. J. J. MORGAN, assistant professor of chemistry at Stevens Institute of Technology, Hoboken, N. J., has been appointed assistant professor of chemical engineering at Columbia University, New York City. Professor Morgan will enter on the work of his new position the coming September.

MAJOR STERLING TEMPLE has received his discharge from the Service at Edgewood Arsenal and is now research chemist for the Roessler & Hasslacher Chemical Co., Perth Amboy, N. J.

COL. WILLIAM H. WALKER has been awarded the Distinguished Service Medal for exceptionally meritorious and conspicuous service. His extraordinary technical ability, untiring industry and great zeal enabled remarkable results to be achieved in the production division of the Chemical Warfare Service in the face of many obstacles.

DR. E. W. WASHBURN, acting chairman of the division of chemistry and chemical engineering, National Research Council, and DR. CHARLES L. PARSONS, chief chemist of the U. S. Bureau of Mines, sailed June 30 for London to attend the meeting of the International Chemical Union beginning July 15. Dr. Washburn will then go to Brussels as chairman of the American delegation of the International Chemical Union to attend meetings of the International Research Council and affiliated organizations beginning July 18.

MR. GEORGE J. YOUNG of the editorial staff of *Engineering and Mining Journal* has been transferred from New York City to San Francisco, where he will serve in the capacity of Western editor for the *Journal*.

Obituary

LORD RAYLEIGH (John Williams Strutt) died on June 30 in London. Born on Nov. 12, 1842, he was educated at Trinity College, Cambridge, where he was graduated as senior wrangler in 1865 and obtained the first Smith's prize of the year. From 1879 to 1884 he was Cavendish professor of experimental physics in Cambridge University, and in 1887 he accepted the post of professor of natural philosophy at the Royal Institution of Great Britain. He was awarded the Nobel Prize for physics in 1904. Many years ago his name became well known throughout Europe by his mathematical and physical papers written under the name of "J. W. Strutt." He used plain and usually home-made apparatus, the accessories being crude and rough, but essentials thoughtfully designed so as to insure in the most perfect manner the object in view. His work was the most productive in chemical physics, theory of gases, flow of liquids, photography, optics, color vision, wave theory, and in electric and magnetic problems of all kinds. It was said of him at the time of his election as Chancellor of Cambridge University in 1908 that "since the death of Lord Kelvin he is the most eminent chemist in Christendom."

MR. BOVERTON REDWOOD, one of the world's foremost authorities in the petroleum industry, died on June 6,

1919. Mr. Redwood was well known in this country as the author of many papers and books on petroleum and allied subjects and as a consultant of high standing on petroleum questions.

MR. WILLIAM G. SHARP, president of the United States Smelting, Refining & Mining Co. since its organization in 1916, died on July 1 at his home in Wenham, Mass.

MR. EUGENE WAUGH, president of the Waugh Chemical Corp., New York City, died recently at New Rochelle, following an operation. Mr. Waugh had been with the General Chemical Co. for fifteen years.

MR. WILLIAM THUM, superintendent of the electrolytic lead refinery of the United States Metals Refining Co., East Chicago, Ind., died on June 28, 1919, at his home in Hammond, Ind., after a brief illness from pneumonia. Mr. Thum was born in Germany in 1863 and received his early education there preparatory to the university. In 1879, however, he came to the United States with his father, F. A. Thum, who was a graduate mining engineer of the Clausthal School of Mines. In 1883 William Thum was made assistant superintendent of the electrolytic copper refining department of the Balbach Smelting & Refining Co., Newark, N. J., and there, in association with his father, he laid the foundation of electrolytic refining in the United States. At that time the Balbach company was using the Parkes process of lead refining, which was superseded by the electrolytic developments of Mr. Thum and his father. In 1904 Mr. Thum was made superintendent of the DeLamar Copper Refining Co., Chrome, N. J., and in 1906 he was sent to Chicago by the United States Metals Refining Co. in the capacity of superintendent of the electrolytic refinery at East Chicago, Ind. This was the first plant of its kind in the United States, although there were others at Trail, B. C., and at Newcastle-on-Tyne. It was at East Chicago that Mr. Thum developed a number of metallurgical processes, some of which he patented. These related to the recovery of bismuth, tellurium and antimony as by-products in electrolytic lead refining; other patents related to apparatus for use in the Pattersonizing process and electrolytic cell for parting Doré bullion. In addition to his attainments in metallurgy Mr. Thum showed unusual versatility in the arts. He painted in oils and water colors. He spoke French, German and English with equal fluency and read Latin with ease. His interest in outdoor life led him to acquire an extensive knowledge of birds and animals and took him to the hunting grounds of Maine. His sympathy with all good movements was shown during the war by his activity in Liberty Loan campaigns, and in the work of patriotic societies of the East Chicago-Hammond district of Indiana.

Current Market Reports

The Non-Ferrous Metal Market

Wednesday, July 9.—Prices have continued to rise during the past fortnight. Anticipation of orders from Central Powers has aided in strengthening the market.

Aluminum.—To be in equilibrium with the other metals on a pre-war basis, aluminum should decline; however, the holders are strong and can be induced to lower prices only to meet foreign competition. A price of 32c. lb. is quoted on 98-99 per cent ingot. Scrap has advanced: Cast 20-24c.; sheet, 21-24c., and clippings, 23-26c. Sheets, 1s gage and heavier, 41c., with some munition offerings at 36c. Powder, 5-ton lots, 45c.

Antimony.—Spot quotations continue at 83c., futures at 81c., and small job lots at 82c. It is believed that no immediate changes will occur.

Copper.—Small sales have been made on electrolytic spot at 19½c., casting at 19c., but late July and August price is at 20c. September futures are reported at 20½c. The Government has liquidated its surplus of 114,000,000 lb.

The aggregate sales per week are large. Wire-drawers are the principal buyers, with brass foundrymen a close second. Japan has been buying heavily, the domestic output there last year having been lower than usual, 95,000 tons,

of which 31,662 was exported. Only 1000 tons was imported from America due to the war embargo.

Copper sheets, hot rolled	lb.	\$28 50	
Copper sheets, cold rolled	lb.	29 50	
Copper bottoms	lb.	36 50	
Copper rods	lb.	29 75	\$21 00
Copper wire	lb.	21 50	21 75
High brass wire and sheets	lb.	23 75	
High brass rods	lb.	22 25	
Low brass wire and sheets	lb.	26 00

S-rap, heavy and ware	lb.	12½	13
S-rap, light and bottoms	lb.	12½	13
S-rap, heavy, cut and crucible	lb.	15½	15½
S-rap brass, heavy	lb.	8½	8½
S-rap brass, casting	lb.	10½	10
S-rap brass, light	lb.	7½	7½
S-rap, No 1 clean brass turnings	lb.	7½	8½
S-rap, No 1 lump turnings	lb.	12½	12½

Lead.—The price remains at 5.4c. for New York and 5.15c. at East St. Louis. Lead sheets cut, 8.5c. lb.

Tin.—It is difficult to gage the market. Spot tin is still quoted at prices around 68c. and 70c., but with importations of tin now free after Sept. 1 and ores that have been shipped on or after June 8 due to arrive here almost any day from South America, the chances are that before long we shall have prices which will come substantially nearer the figures now quoted for shipment tin, which is at about 52c. lb.

Zinc.—Spot spelter at East St. Louis is tending to advance from 7½ to 7½c. lb., New York, 7.4c.

The Iron and Steel Market

Steel mill operations during the first half of July averaged between 65 and 70 per cent of capacity, against an average of about 60 per cent in June and a low point of approximately 50 per cent at the middle of May. As the increase in production has not altogether kept pace with the increase in buying that began just before the middle of May, it is clear that the recovery in the steel market is of very substantial character.

Demand has been distributed far from uniformly among the various lines of finished product, the divergence being due, of course, to varying conditions among the different classes of consumers consequent upon the war ending so recently. Some consumers were free buyers during the war, others have since become large buyers and still other prospective buyers, chiefly of the investment class, have not yet been ready to act.

Easily the most active line in finished steel products is oil country goods, the chief product of the lap weld departments of the pipe mills. This demand was rather heavy in the early months of the year and has lately been of such large volume as to fill the lap weld departments far ahead, a few mills being now sold up practically to the end of the year. Judged by all precedents, this demand is abnormally large, its expansion being due to the heavy demand for oil and oil products, the high market price and the increased number of wells necessary to produce the required output.

AUTOMOBILE TRADE ACTIVE

Next in point of activity is the automobile trade, which requires a somewhat larger tonnage of steel than at any time in the past. The automobile trade's demand is reflected most clearly in the sheet and cold drawn industries. Sheet mills are operating at more than 80 per cent of capacity, chiefly by reason of the demands of the automobile trade, as the demand for sheets for building purposes is relatively light. Makers of cold drawn shafting and screw

stock are operating at about 80 per cent of capacity, against only about 60 per cent 30 days ago, and attribute the increase in their business chiefly to demand from the automobile trade. Their orders for bars are the best the bar mills are receiving.

Apart from these classes of demand, there is approximately a normal volume of demand for steel products from jobbers and from many classes of manufacturing consumers.

WHERE DEMAND IS LIGHT

Where demand is light is among the railroads, the shipyards and investors generally who engage in large construction undertakings. There is practically no railroad demand at all. Even the 300,000 tons of rails it was reported several weeks ago the Railroad Administration would order, to round out its work for the year, have not appeared in the market. There would be no other buying of importance by the Railroad Administration, and the question is when the railroads will be placed in position to know what they will be justified in doing by way of improving their facilities, and what they will do when their position has been assured. While operating control of the roads is likely to be restored to the owners about Aug. 1, with the Government guarantee as to earnings running to the end of the year, the conditions under which the roads will operate in future, as to freight rates and the credit they can command, await action by Congress. The steel trade is of the impression that when railroad buying begins it will run rather to material needed for extensions of road and improvement of terminals than to freight cars.

Shipbuilding is at a greater rate than ever before, probably at between 600,000 and 700,000 tons deadweight per month, involving the consumption of 200,000 to 250,000 tons of steel, chiefly plates, per month, but the demands upon the mills are not in keeping, because stocks of steel at shipyards are being drawn upon.

IMPROVEMENT IN CONSTRUCTION WORK

In construction work there is a steady improvement, as has been shown by the monthly returns of the Bridge Builders' and Structural Society and by various detached pieces of information as to contracts lately let or about to be let, but the pace even at this date is far below normal. It is true that much "building" activity is reported from practically all sections of the country, but this building runs largely to dwelling house construction and repair work generally. It is not, in general, the class of building that involves the consumption of much steel. As a matter of fact the activity is unfavorable to the steel industry rather than favorable, because with the supply of labor limited and also the supplies of some classes of material the facilities are pre-empted and construction work involving the use of large quantities of steel may be discouraged or postponed. The basic principle is that there is several years of work to be done, and the more pressing work will delay the less pressing. Thus dwelling houses will take precedence over bridges and skyscraper hotel and office buildings.

STEEL PRICES

The steel prices that became quotable March 21 are now firmly established. A considerable proportion of the steel bought in May and the fore part of June was at cut prices, though throughout the period the March 21 prices were regarded, generally speaking, as "the market." In the past few weeks this shading has been diminishing and it is now of very small proportions, except in plates, which present a relatively hopeless case, capacity being in excess of any easily conceivable demand. The condition has so changed that there is now no fear of any general decline in the market, while on the other hand, there are predictions in some quarters that advances in some lines will occur in the near future. It has now become generally known that the Steel Corporation some time ago adopted a definite policy, setting itself against any steel price advances, this year at least, and the question remaining is whether the independents in any line will be willing and able to engineer an advance of their own, thereby decreas-

ing their prestige among buyers and forcing the Steel Corporation to choose between picking its customers or becoming badly oversold.

In view of the course the steel market has frequently pursued in the past, the maintenance of the general price level during May and June was remarkable. Many producers, including the Steel Corporation, refused absolutely to cut prices, being willing that mills disposed to cut should fill up. This forbearance was due in part to recognition of the fact that the business left on mill books at the conclusion of the war was very irregularly distributed, so that in the early months of the year some mills had been forced to operate at much lower rates than others. Thus it was only fair that mills should be allowed to buy their way into the market, while if the cuts had been met generally the sequel would simply have been additional cuts.

PIG IRON

The pig iron market has become well established. For several months consumers had been extremely desirous of reducing their stocks, and this policy was pursued to such length that many consumers found themselves with stocks far below normal, some with no stocks at all. A buying movement due partly to this situation and partly to increased consumptive requirements began the latter part of May. This movement appears now to have run its course, but it has left the furnaces that are in blast fairly well sold up, a few furnaces being sold up practically to the end of the year. The competition among districts has practically disappeared and prices in all districts are now on a fairly stable basis, with scarcely any prospect that prices will decline in the near future and a bare possibility that they will advance before the end of the year. An advance, however, is somewhat improbable so long as there are many idle furnaces, and should demand develop these furnaces would doubtless sell at the market, or a shade lower, to accumulate backlog business upon which to blow in.

The Chemical Market

New York, July 11, 1919.

Following the recent advance of *caustic soda* to \$3.30 per cwt., the United States Alkali Export Association last week raised the quotation on light 59 per cent *soda ash* to \$1.90.

Muriatic acid is gaining strength in the market although as yet no quotable change is announced. Dyestuff manufacturers are the principal buyers on the domestic end with Cuba still the main export source. Another acid which is feeling the general improvement is *sulphuric*, quantities of it being shipped to South America, whence emanates also a good inquiry for *caustic soda*.

Heavy sales of *potassium carbonate* are reported, most of it going for export. Stocks of *potassium prussiate*, yellow, are limited. The market is, therefore, advancing, now being 30-35c. per lb., an increase of 3c. *Sodium prussiate*, yellow, is in the same category. After a drop to 25c. per lb. last week, dearth of supply has brought the quotation up to the previous level of 35c.

Manufacturers are quoting *citric acid* at 98c. per lb., but find it difficult to deliver because of short stocks. Second hands are quoting \$1.05 per lb.

OILS—With no oil available in quantities until August, business in linseed oil is practically at a standstill. Quotations on raw linseed oil in carlots, August delivery, range from \$1.90 to \$2.14 per gal. against \$1.88-1.90 at last writing. Other vegetable oils are similarly situated, and the market is highly speculative. Thus far the signing of the peace terms has had no particular effect on trading, but as soon as Germany and Austria call for their badly needed fats further advances are to be expected.

Menhaden fish oils are reported scarce for spot but satisfactory for futures. The catches have been good, but the fish are lean and yield little oil. Soap, paint and varnish manufacturers are the heavy domestic users, while requests from Europe continue to be general. Winter pressed Menhaden is now quoted at \$1.20-\$1.25 per gal. against \$1.10 two weeks ago.

COAL-TAR PRODUCTS—Among the crudes, benzol, solvent naphtha and toluol are the most active. Benzol continues in heavy request by rubber-tire manufacturers. Aniline oil is perhaps the strongest item among the intermediates. Nearly all manufacturers have their production for this month sold and few are offering any for sale during the remainder of the year. Japan is buying aniline oil and dimethylaniline in quantities. Salicylic acid—which has been selling below the cost of production—has advanced five cents, to 25c. per lb. in carlots for the technical grade, owing to resale lots being off the market. It is rumored that the Government has on hand something like 20,000,000 lb. of phenol which will be turned over to two leading manufacturers for disposal at a figure officially fixed. Paratoluidine, H-acid and alpha-naphthylamine are having good sales, with ortho-toluidine and ortho-nitro-toluol beginning again to show signs of activity.

NAVAL STORES

After a drop from \$1.10 per gal. to \$1.02 during the past two weeks spirits of turpentine is again rising, at this writing having reached \$1.05. The market in Savannah is also much firmer. The pale grades of rosins continue in active demand, with Holland the main customer. Owing to its increasing use in flotation processes, pine oil is in good demand. It is now quoted at 75c. per gal., a rise of 5c.

SHELLAC

The shellac market is still very much involved. Cables from Calcutta are from a week to ten days late and shed little light on the true situation. Dealers are merely endeavoring to supply regular customers and do not know when the situation will be relieved.

One dealer is quoting October-December delivery of TN at 90c., while another, on the same delivery, quotes 82c.; orange, superfine, 85c.; A.C. garnet, 72c.; and bleached, bone dry, 95c.

Chicago, July 9, 1919.

All heavy chemicals have either advanced a little or remained steady, coal-tar products show no fluctuation, vegetable oils are all up sharply and naval stores and flotation oils are in great demand at prices that seem very high.

HEAVY CHEMICALS—Caustic soda and soda ash, under the impetus of fairly heavy export orders to the Orient, are held strictly at market figures; caustic being quoted at 3c. to 3½c. works for the solid and 4c. for the granulated, ash at 2c. Bleaching powder (calcium hypochlorite) is still quoted at 2c., with indications pointing to an advance.

Sulphuric acid is in heavy demand, sales being made at from \$18 to \$19 for 66-deg. Stocks of this staple are low, a combination of labor trouble and high cost of raw materials tending to curtail production. Muriatic acid is moving freely at \$22; nitric, while not in such heavy demand, is quoted at 10½c. for 40-deg.

Potassium carbonate is expensive, because of dealers' stocks having been absorbed by export orders, the effect being a rise from the 13c. four weeks ago to 22c. to-day. Sodium nitrate is changing hands at \$4.25 for crude, \$5.60 for double refined, the demand being ordinary.

COAL-TAR PRODUCTS—Slight tendency of prices to stiffen is the only notable feature in this line, 90% Benzol being quoted at 25c. to 26c., 100% at one cent higher. Solvent naphtha is quoted at 24c. and commercial xylol at 26c. No changes of moment are noted among the intermediates, trading in the entire coal tar line being merely normal.

VEGETABLE OILS—Recent sharp advances have had a decidedly repressive effect on sales, users limiting their purchases strictly to current requirements. All sales are of spot stock for immediate delivery, and it is unlikely that contracts will be placed at current figures.

Soya bean oil is quoted for July-August delivery in Chicago at 18c., coconut oil, Manila, at 18½c., sellers tanks. China wood oil brings 24c. in less than car lots, spots and futures being offered in cars at 21c. A definite shortage seems to have developed in corn oil, stocks going freely at 21c. and sellers tanks from the West at 19c. Cotton oil shows little activity at 25c. An advance in palm oil has

been prevented by expected receipts from Europe, price being 17½c.

FLUTATION OILS, NAVAL STORES—Naval stores are rising in price so rapidly that sales are being curtailed. Pure steam distilled pine oil is now held at 85c. in carloads, 90c. for less, for .933 test, an advance of 7c.—68c. to 75c., in car lots. Pine tar oil remains at 36c.

Turpentine continues to fluctuate between \$1.05 and \$1.10, the demands of consumers being sufficiently heavy at this figure to prevent any early decline in price. Stocks are reported to be very short.

St. Louis, July 10, 1919.

HEAVY CHEMICALS—An almost insatiable demand for sulphuric acid on the part of the fertilizer manufacturers and for niter cake on the part of the steel manufacturers is the outstanding development of the past two weeks. Producers report that while there are sufficient supplies of both these chemicals (and probably will be throughout the year) such large quantities are being contracted for and inquiries are so numerous that it is difficult to understand where the heavy tonnages sought for are going.

The only important price change reported since the last review is a 50c. per ton advance in 60% sulphuric acid, which is expected to result in an upward change in the price of other grades. An indication of the proportions the demand for 60% sulphuric is assuming may be had in the fact that one of the buyers in the local market has just closed a deal on the basis of an annual consumption of 15,000 tons as compared to a consumption of 4,000 tons last year, while another deal was consummated involving delivery of 100 tons monthly to a consumer who heretofore has required only 400 tons yearly. The 66%-grade is less active, the price still being \$18 a ton. There is no change in the market for oleum.

Word is brought here by men in close touch with the fertilizer industry that because of the depletion of farm lands during the war, through the lack of commercial fertilizer, an unprecedented demand for fertilizers of all sorts now exists and is likely to continue for some time.

Muriatic Acid is not moving very rapidly, the price remaining at \$22 a ton for 18%. Sodium sulphate (salt cake) has been selling heavily to glass manufacturers at \$16.50 to \$18, the former for heavy-tonnage contracts. There is more than a plentiful supply of salt cake, but from the manner in which the glass industry is preparing for the season to open on Aug. 15 it is expected present prices will remain firm.

Sodium bisulphate (niter cake):—Steel manufacturers who because of the scarcity of sulphuric acid during the war turned to niter cake for steel-pickling purposes will continue to use that chemical in place of sulphuric acid. Heavy sales of niter cake for this purpose are reported at \$3.50 to \$4 a ton. These prices are said to be representative of the market, the higher prices quoted in the last report representing special sales.

Nitric acid is the one item in the heavy chemical market in which a price decline is looked for. It is expected to occur on Aug. 1, due to the decline in the price of nitrate of soda. What little business is being done in this branch of the market is reported on the basis of 10c. to 10½c. per lb. for the 38° Baumé grade.

Zinc chloride is moving in heavy tonnage out of the local market to the tie-treating centers. As in the case of sulphuric acid, some consumers are trebling their normal requirements of zinc chloride. One transaction is reported involving a monthly shipment of 700,000 lb. to a plant which hitherto has been using only 140,000 lb. The price is firm at 4c. per lb. for the 50% solution, which is the only grade in which business on a large scale is being done here.

Zinc oxide was again quoted on formally by Mid-West producers, on July 1, but unlike previous announcements the list is subject to change without notice, though contracts are being written for delivery over the remainder of the year at the current prices, 8c. to 9c. per lb., according to lead sulphate content, in car lots; half a cent higher for smaller quantities.

Waxes

Prices based on original packages in large quantities

Bee-wax, natural crude, yellow	lb.	\$0.43	\$0.45
Bee-wax, refined, yellow	lb.	48	55
Bee-wax, white pure	lb.	65	68
Carnauba, No. 1	lb.	80	85
Carnauba, No. 2, regular	lb.	75	82
Carnauba, No. 3, North Country	lb.	61	65
Japan	lb.	181	21
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	06	07
Paraffine waxes, crude, scale 124-126 m.p.	lb.	06	06
Paraffine waxes, refined, 118-120 m.p.	lb.	671	08
Paraffine waxes, refined, 128-130 m.p.	lb.	89	10
Paraffine waxes, refined, 133-135 m.p.	lb.	11	12
Paraffine waxes, refined, 135-137 m.p.	lb.	121	23
Stearic acid, single pressed	lb.	22	25
Stearic acid, double pressed	lb.	23	25
Stearic acid, triple pressed	lb.	24	27

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940	gal.	\$0.75
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	45
Pine tar oil, ref., sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	33
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	58
Pine tar, ref., thin, sp. gr. 1.080-1.060	gal.	34
Turpentine, crude, sp. gr. 0.900-0.970	gal.	61
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990	gal.	24
Hardwood oil, f.o.b. Mich., sp. gr. 1.00-1.08	gal.	24
Pineewood creosote, ref.	gal.	48

Naval Stores

The following prices are f.o.b. New York, for carload lots.

Rosin B-D, bbl.	280 lb.	\$16.00	\$16.25
Rosin E-1	280 lb.	16	15
Rosin K-N	250 lb.	17.90	19.50

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15 in.	100 lb.	\$2.45
Angles, 3 to 6 in., 1/2 in. thick	100 lb.	2.45
Truss, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.66
Rivets, structural, 1/2 in. and larger	100 lb.	4.20
Rivets, conehead for boilers, 1-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.35
Sheets, No. 28 blue annealed	100 lb.	3.55
Sheets, No. 28 prime used	100 lb.	5.70
For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c. all gages.		

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

California

CLAREMONT—The trustees of Pomona College have received a donation of \$100,000 for the construction of a chemistry hall.

LINDSAY—The city voted \$85,000 bonds for the construction of a gas system. Olmsted & Gillette, 1112 Hollingsworth Bldg., Los Angeles, engineers.

SACRAMENTO—The city Commissioners voted \$1300,000 bonds for the construction of a filtration plant for the municipal water system. T. Couter, Commissioner of Public Works. Noted Jan. 15.

Connecticut

WATERBURY—The city will install a chemical laboratory in the basement of the 1-story garage which it plans to build. Estimated cost, \$60,000. Cass Gilbert, 244 Madison Ave., New York City, N. Y., architect.

Florida

ARCHER—The Archer Cane Manufacturing Co. plans to build a large cane mill for making high grade syrup. A. D. Lindsay, president.

KEY WEST—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for installing oil burning equipment here, to the South Florida Contracting & Engineering Co., Eaton and Elizabeth Sts. Estimated cost, \$5,800.

WEST PALM BEACH—The State Board of Health plans to install a modern filtration plant. Estimated cost, \$75,000. Address G. W. Simmons, Jr.

Illinois

CHICAGO—Sears, Roebuck & Co., Arlington and Homan Aves., plans to build a 5-story paint factory on Kostner Ave. and Fillmore St. Estimated cost, \$250,000. G. C. Nimmons & Co., 122 South Michigan Ave., architect.

GREAT LAKES—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for remodeling the sewage disposal plant here, to Hansen Bros. Co., 126 North Dearborn St., Chicago. Estimated cost, \$17,481.

Indiana

INDIANAPOLIS—The Smith Dye Works, 531 Warsaw St., has awarded the contract for the construction of a 1-story, 30 x 65-ft. dry cleaning plant, to T. A. Moynahan, 1947 Broadway.

NEW ALBANY—The Calumet Fertilizer Co. has awarded the contract for the construction of a 48 x 65-ft. plant, to E. Embrey, New Albany. Estimated cost, \$15,000. Noted May 15.

Iowa

STRAWBERRY POINT—The town plans to build one mile of sanitary sewers and a sewage disposal plant. W. F. Pinecke, mayor. H. R. Green, Union Block, Cedar Rapids, engineer.

Kansas

TREECE—The Early Bird Mining Co., Baxter Springs, will install an additional jig plant and is in the market for rolls, elevator pulleys, belting, shafting, etc. C. Eldred, superintendent.

Kentucky

ASHLAND—The Board of Water Commissioners will receive bids until July 24 for the construction of a 2,000,000-gal. filtration plant and a centrifugal pumping plant of seven units. Alvord & Burdick, 4 South Dearborn St., Chicago, Ill., engineer. Noted May 15.

Louisiana

BATON ROUGE—The Aluminum Ore

Co., East St. Louis, Ill., has acquired 227 acres near here and plans to build an aluminum ore refinery. Estimated cost, \$1,000,000. C. E. Rudisill, c/o owner, engineer.

Maryland

CUMBERLAND—The American Cellulose Chemical Manufacturing Co., Ltd., plans to build an addition to its plant. Estimated cost, \$1,000,000.

Massachusetts

PALMER—The Clinton-Wright Wire Co., Hammond St., Worcester, plans to build a 1-story steel plant here. Estimated cost, \$100,000.

TURNERS FALLS—The Esleeck Manufacturing Co. plans to build a 5-story addition to its paper manufacturing plant here. Estimated cost, \$75,000.

Michigan

DETROIT—The Detroit Seamless Tube Co., 841 West Jefferson Ave., has awarded the contract for two 1-story, 90 x 550-ft. additions to its plant, to be equipped with modern machinery for the manufacture of steel tubes, to A. A. Albrecht & Co., 1130 Fenobosc Bldg. Estimated cost, \$1,700,000.

Missouri

MACON—W. H. Martin, city clerk, has awarded the contract for the construction of a sewage disposal plant, to W. McClurken, 3807 Westminster Ave., St. Louis. Estimated cost, \$18,000.

ST. LOUIS—The St. Louis Surfactant & Paint Co., Arlington and Terminal R.R., has awarded the contract for the construction of a 2-story, 28 x 47-ft. factory at 5438 Hazel St., to the W. R. Wilson Building Co., Odd Fellows Bldg. Estimated cost, \$10,000.

WACO—The Union Metal Mines Co. plans to build a new concentrating mill at its mine in Waco Field, Kan., and is in the market for material for same. P. B. Bitter, general manager.

WEBB CITY—The Orange Mining Co. plans to enlarge its plant in every department and is in the market for crushers, rolls, hoists and compressor. H. H. Wallower, supt.

Montana

HELENA—The State Board of Examiners will soon award the contract for the construction of a laboratory for the Board of Health. Halre & Link, Power Bldg., architects. Noted April 1.

Nebraska

LINCOLN—The Lincoln Paint & Color Co., 811 M St., will rebuild its 2-story, 50 x 80-ft. paint factory recently destroyed by fire, entailing a loss of \$25,000.

New Jersey

TRENTON—The city plans to build a sewage disposal plant. Estimated cost, \$500,000. J. R. Fell, 134 North Montgomery St., engineer.

TRENTON—The Hamilton Rubber Co., Clinton and Mead Sts., has awarded the contract for the construction of a 3-story, 75 x 75-ft. plant, to Aitken & Bebbington, 115 South Stockton St. Estimated cost, \$29,000.

TRENTON—The Luzerne Rubber Co., Muirhead Ave., has awarded the contract for the construction of a 2-story, 50 x 75-ft. addition to its rubber plant, to N. A. K. Bugbee Co., 204 East Hanover St. Estimated cost, \$13,000.

TRENTON—The Stokes Rubber Co., Taylor St., has awarded the contract for the construction of a 1-story, 50 x 100-ft. addition to its plant, to N. A. K. Bugbee Co., 204 East Hanover St. Estimated cost, \$8500.

New York

ALBANY—Dr. H. M. Biggs, Commissioner of Health, State Department of Health, Capitol, Albany, will receive bids

until July 22 for installing apparatus and equipment in the laboratory building here, to include experimental extractions and distilling apparatus, water stills, autoclaves, etc. Estimated cost, \$6000.

POUGHKEEPSIE—The State Hospital Commission, Capitol, Albany, has awarded the contract for altering and building additions to the water supply system at the Hudson River State Hospital, here, to the Baker-Dunbar-Allen Co., Stock Exchange Bldg., Philadelphia, Pa. Plans include installing additional filters, etc. Estimated cost, \$52,000. Noted June 1.

North Carolina

CLINTON—The Sampson Oil & Fertilizer Co. plans to build a fertilizer factory. Estimated cost, \$75,000. American Machine & Manufacturing Co., Greenville, S. C., architect.

Ohio

CLEVELAND—The Cleveland Electro Metals Co., 421 Guardian Bldg., has awarded the contract for the construction of a 2-story, 40 x 50-ft. addition to its 1-story at 231 West 18th St. to the Drummond Miller Co., 422 Guardian Bldg. Estimated cost, \$6000.

CLEVELAND—The Crucible Steel Castings Co., Canal Rd. and Champlain Ave., plans to build a 2-story, 125 x 300-ft. factory on Almira and Denison Aves. Estimated cost, \$100,000.

CLEVELAND—The Ideal Tire & Rubber Co., East 17th St. and Euclid Ave., plans to build a 3-story, 100 x 200-ft. addition to its factory on Warren Rd. Estimated cost, \$125,000.

CLEVELAND—The Vitreous Enameling Co., 6800 Grant Ave., has awarded the contract for the construction of a 1-story, 90 x 120-ft. factory on East 71st St. and Grant Ave., to W. Dunbar Co., 8201 Cedar Ave. Estimated cost, \$35,000.

CLEVELAND—The National Copper & Smelting Co., Rose Bldg., plans to build a 2-story, 75 x 100-ft. addition to its plant and Nickelplate Ry. Estimated cost, \$25,000.

COLUMBUS—The Timkin Roller Bearing Co., Duober Ave., Canton, has acquired a site and plans to build a 300 x 500-ft. branch plant here. Estimated cost, between \$1,000,000 and \$1,500,000. H. H. Timkin, president.

DAYTON—The Dayton Steel Co., Howell and Parker Sts., plans to build a factory for the manufacture of fabricated structural steel and bridges. Estimated cost, \$35,000.

Pennsylvania

PHILADELPHIA—Firth & Foster, Emerald and Foster Sts., have awarded the contract for the construction of a 1-story, 64 x 68-ft. dye house, to F. A. Havens Co., 845 North 19th St. Estimated cost, \$20,000.

PITTSBURGH—The Basic Mineral Co., 824 Columbus Ave., N. S., is having plans prepared by Leffer & Schubert, architects, North Side, for the construction of a 2-story, 75 x 75-ft. addition to its plant on Columbus Ave., for the manufacture of flux and deodorizer for melting metals. Plans include laboratory, mill and electric furnaces. Estimated cost, \$25,000.

WILLIAMSPORT—The J. K. Mosser Tannery Co., a subsidiary of the J. K. Mosser Leather Co., Newberry, will soon receive bids for the construction of a 6-story, 150 x 196 x 202-ft. tannery, on Arch St., here.

South Dakota

DEADWOOD—The Capital Gold Mining & Milling Co., 405 Brandies Theatre Bldg., Omaha, Neb., plans to build an air compressor plant, power line, etc., and is in the market for complete equipment. Estimated cost, \$10,000. R. M. Harrop, general manager.

Tennessee

COLUMBIA—The Victor Chemical Co., Fisher Bldg., Chicago, Ill., plans to build a chemical plant near here. W. B. Brown, vice-president.

Washington

KELSO—The Union Oil Co. of California, Mills Bldg., San Francisco, has purchased a site and plans to build an oil distributing plant, including one 20,000-gal. distillate tank, one 20,000-gal. gasoline tank and one 20,000-gal. coal oil tank, at North Kelso. C. C. Ireland, representative.

SEATTLE—The West Coast Rubber Co., 4050 Occidental Ave., has awarded the contract for the construction of a 1-story, 112 x 153-ft. factory for the manufacture of rubber products, on 7th and Mercer Sts., to J. W. Johnson, 171 McIlwain St. Estimated cost, \$26,000.

SPOKANE—The International Steel Co. has purchased a site along the Chicago, Milwaukee & St. Paul R.R. and plans to build a steel rolling mill, to be equipped with electric furnaces. Estimated cost, \$100,000. L. L. Bair, president.

Wisconsin

CAMBRIDGEVILLE—The United States Fertilizer Co., c/o Glue Co., has awarded the contract for the construction of a 2 and 3-story, 67 x 219 and 50 x 50-ft. fertilizing plant, to P. Riesen and Sons, 1018 Humboldt Ave., Milwaukee. Estimated cost, \$100,000. Noted July 1.

Ontario

HAMILTON—The Quaker City Chemical Co., Philadelphia, Pa., plans to build a 4-story, 60 x 120-ft. chemical plant here. Estimated cost, \$120,000. C. H. Mackay, Hamilton, Ont., engineer.

LONDON—C. S. Hyman, Richmond St., plans to build a new tannery. Estimated cost, \$300,000. W. F. D. Jarvis, manager.

SWEN SOUND—The Dominion Oil Co. will receive bids until July 15 for the construction of a 3-story, 38 x 70-ft. plant for the manufacture of oils, greases and soaps. Estimated cost, \$30,000.

PORT ARTHUR—The Carleek Pulp Mill plans to build an extension to its plant, in order to increase the capacity to 350 tons.

TORONTO—Baldwins of Swansea, Wales, England, plans to build steel rolling mills on Ashbridges Bay, here. Estimated cost, \$3,000,000.

WINNIPEG—The City Council plans to install filters at the waterworks. Estimated cost, \$300,000. Address I. F. Smith.

Quebec

MONTREAL—The T. Davidson Manufacturing Co., 187 Delisle St., has awarded the contract for the construction of a 75 x 100-ft. factory for the manufacture of enamel wares, to A. F. Byers & Co., 340 University St. Estimated cost, \$75,000.

Manufacturers' Catalogs

THE TRUMPOUR-WHITEHEAD BRASS & COPPER CO., INC., has recently issued a booklet on monel metal. Of particular interest is the result of tests given this metal in the College of the City of New York in 1913, which are described.

THE ALLIS-CHALMERS MANUFACTURING CO., Milwaukee, Wis., has published illustrated catalog No. 107 descriptive of concentrating machinery and equipment. This catalog contains a brief treatise on principles of concentration, together with flow-sheets of typical mills in different parts of the country. An attractive booklet is also being distributed on the works and products of the company.

THE CELITE PRODUCTS CO., New York City, has just issued Bull. B-13 describing the use and application of Sil-O-Cel plastic cement for preventing heat losses and increasing the capacity of high-temperature equipment. Copies will be sent on request.

THE METAL & THERMIT CORP., New York, N. Y., has issued a folder entitled "How Thermit Healed My Broken Jaw," which illustrates the operations involved in making a thermite weld on the 13-ton broken upper jaw of an alligator shear used by Jos. Joseph & Bros. Co., Modena, Pa. The break welded was 50 in. in length and varied from 4 to 20 in. in thickness.

HUNGERFORD & TERRY, INC., calls attention to a general catalog of Hungerford filters which is now ready for distribution. This publication describes the full line.

THE BUFFALO FORCE CO., Buffalo, is distributing Section No. 400 on fans, blowers and exhausters, which are illustrated and described.

THE HOOKER ELECTROCHEMICAL CO., New York, has gotten out new folders on muriatic acid, bleach and liquid chlorine which the company will be glad to send to any one interested.

THE DORR CO., New York and Denver, has published Bull. No. 13 describing the Dorroc pump. This is a 16-page bulletin containing tables of dimensions, weights, capacities, etc., and instruction for operating and illustrations.

THE JEFFREY MANUFACTURING CO., Columbus, Ohio, announces a new catalog No. 34 on standard iron conveyors. This catalog contains 77 pages, devoted to installations showing standard steel and wood apron conveyors in service in various industries, specifications, general dimensions and other important data.

THE IRVING IRON WORKS CO., Long Island City, has issued a booklet called "Irving Subway" which is the fireproof metallic ventilating flooring.

THE GENERAL CHEMICAL CO., New York, has gotten out an attractive book which is an extended report covering twenty years, from March 1, 1899, to March 1, 1919, and tells of its origin, organization, facilities, field of activity and accomplishments.

THE CEMENT GUN CONSTRUCTION CO., Chicago, Ill., has just issued Guide Book No. 6, entitled "We Do the Work," with illustrations of recent cement gun work.

THE WILLIAM J. POLLOCK CO., Youngstown, Ohio, has just received from the press Vol. No. 21, which contains a series of photographs of modern blast-furnaces.

THE BASTIAN-BREASING CO., Chicago, Ill., "Rego Welding and Cutting Apparatus" is the title of a new publication just issued by this company.

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis., calls attention to a new bulletin on the value of accurate measurements of gases and air in a gas plant, coke oven plant, steel plant or chemical plant.

THE AUSTIN CO., has just issued a new catalog of standard buildings which contains drawings, illustrations and specifications of each of the ten standard types, together with complete information concerning the scope of Austin Building Service.

THE COLORADO IRON WORKS CO., Denver, Colo., announces pamphlet No. 9-C on the improved impact screen for the wet or dry sizing of all kinds of materials.

THE ROCKWELL CO., New York, has published Bull. No. 42 on cost of heating of steel, which deals with fuel and labor conservation in a forge shop; the "economizer" forge is illustrated and described. In Bulletin No. 31 the application of the economizer principle of the economizer forge is fully illustrated and described. Copies will be sent upon request.

R. D. MUTTALL CO., Chicago, Ill., has gotten out pamphlet on "Pedigree Gears," which contains illustrations and descriptive matter.

THE MERRILL CO., San Francisco, Cal., calls attention to a new catalog on "The Nordstrom Lubricated Plug Valve."

THE GEO. C. VIETTO MACHINERY CO., Pittsburgh, Pa., has issued leaflets on standard bucket elevators, self-traction trucks, self-feeding bucket loaders, etc.

THE GIFFORD-WOOD CO., Hudson, N. Y., Bull. 42 on Field and Basin Saws illustrates and describes the many different types and what users say of their performance.

THE STANDARD SPIRAL PIPE WORKS, Chicago, Ill., is distributing Cat. No. 7, which deals with smooth bore reinforced spiral pipe, valves, cast-iron fittings, special steel fittings, hydraulic supplies, forged steel flanges and drop forgings.

THE WELLMAN & SEEVER-MORGAN CO., Cleveland, Ohio, has issued Bull. No. 17 on the Hughes Mechanical Gas Producer.

THE THOMPSON-STARRETT CO., New York, has just published two very interesting brochures. The first brochure, "Architect and Industrial Construction," illustrates and describes the many types of buildings put up by this company, including the new building at New York University, museums, hotels, exhibit buildings, power houses, forging and machine plants and manufacturing plants of all kinds. The title of the second brochure is "Building for Victory," by Col. W. A. Starratt. This is a reprint of an article which appeared in Scribner's for November, 1918, which describes and illustrates the work of this company on the \$50,000,000 powder plant at Nitro, West Virginia, which was built under the direction of D. C. Jacking, acting as director of explosives for the Ordnance Department, and the New York Cantonment, which was built in 100 days.

THE TIDE WATER OIL CO., New York, has issued a booklet on Fuel Oil, which is for use by engineers, plant managers and all those who are interested in fuel oil and its various applications for raising steam for power, for furnaces, gas making, etc. It contains formulae for computing the relative cost of fuel oil and coal, and comprehensive data on the instruments, tanks and other appliances necessary for its most efficient use.

Industrial Notes

THE ELECTRIC FURNACE CO., Alliance, Ohio, has just shipped one of its standard hose tilting type furnaces to the United States Navy Yard at Washington, D. C. to be used in the Government brass foundry there. The furnace is provided with a motor-operated tilting mechanism and has a maximum hearth capacity of 200 lb. The shell is 7 ft. in diameter and the furnace is rated at 105 kw in electrical capacity.

MR. T. LINSEY CROSBLEY, who has been associated for a number of years with J. T. Donald & Co., consulting engineers, has taken over the Toronto office and laboratory of that firm at 43 Scott St., and will there carry on the business of consulting chemists and chemical engineers. He does general consultation work. Mr. Crosbley has specialized in municipal chemistry and the technology of pulp and paper manufacture.

THE AUSTIN CO., Cleveland, Ohio, announces the engagement of Mr. O. D. Conover as production and sales engineer on foundries and steel plants. Mr. Conover was formerly vice-president and chief engineer of the T. W. Austin Co., Cleveland, and of New York and production manager of the Luddum Electric Furnace Corp. Mr. Conover's headquarters will be at the Cleveland office of the Austin Co.

The first heat of steel from the Greaves-Elchells electric furnace at the Leeward Island Navy Yard, Philadelphia, was made July 1. The furnace was recently installed in the new foundry by the ELECTRIC FURNACE CONSTRUCTION CO., Philadelphia, Pa. The Electric Furnace Construction Co. also announces that it has received an order for an electric furnace for the manufacture of ferro-alloys for Spain, from the Sociedad Española de Construcción Química. A victory committee of which consists of the firms of Sir W. G. Armstrong Whitworth & Co., Vickers, Ltd., and John Brown & Co., Ltd., is the first furnace of its kind to be erected in Spain for converting that country's natural ores into ferro-alloys.

THE J. P. DEVINE CO., Buffalo, N. Y., has recently completed or has in process of construction several new additions to its plant for the manufacture of chemical apparatus. One of the additions, 30 ft. x 100 ft., is housing the department for the assembling of vacuum pumps; another, 30 ft. x 100 ft., now in process of construction, will enlarge the general assembling department. Construction is proceeding on a new foundry, 90 ft. x 225 ft., which will give greatly increased facilities for making large castings. Employment will be provided for 200 additional men.

The C-H Messenger, the shop newspaper of the CUTLER-HAMMER MFG. CO., contains a recent issue of photographs and names of many of the companies in the chemical industry in the recent war. The list is incomplete, but there are nearly 300 names on this Roll of Honor.

THE MORGAN CONSTRUCTION CO. announces that the Cambria Steel Co. has installed 51 Morgan gas producers at the Franklin furnaces at the Weirton Steel Co. of Weirton, W. Va., and is building an entirely new open-hearth and blooming mill plant containing 27 Morgan producers. This equipment has been purchased by four British steel plants this year.

THE GEORGE J. HAGAN CO., Pittsburgh, Pa., has closed a contract with a French company for the purchase of the rights in the Hagan Co.'s patented devices for sheet, tin-mill and job-mill furnaces. The contract was closed for a large cash consideration and the French company's rights in all European countries. The Hagan Co. reports important sales of its patented furnaces to the Eastern Rolling Mill Co., Baltimore, the American Sheet & Tin-Plate Co., Gary, the Lehigh Steel Works, Canton Sheet Steel Co., Otis Steel Co., and the Newport Rolling Mill Co.

MESSRS. H. D. STALEY and G. A. FISHER, of the business known as the name of the Western Steel & Engineering Co., 37 Montgomery St., San Francisco, have been appointed California representatives for the Iron and Filters Corp.

THE STEPHENS-ADAMSON CO., Aurora, Ill., announces its new representative in the San Francisco district. The firm of Bannan, Dodson, McIntyre, Inc., 317 Market Street, San Francisco, will have charge of the engineering sales work in this territory.

THE NEW JERSEY ZINC CO. of New York has just established warehouses in San Francisco and Los Angeles from which its products will be distributed to its trade on the Pacific Coast.

New Chemical Laboratory For Cornell University

AN UNNAMED donor has agreed to build a new chemical laboratory for Cornell University which shall be adequate to its needs. The University has been sorely crippled by the loss by fire of the major portion of its old laboratory, and unless present plans miscarry the new structure, which will cost over \$1,000,000, will be ready for occupancy by the spring of 1920. This proper housing of the learned and able Cornell staff, and its body of students of chemistry, is a matter for congratulation on behalf of all who have the welfare of chemistry in America at heart. Speculation is rife among the alumni as to the benefactor's name, and while President SCHURMAN is firm in his silence in this respect, it is believed by many that CHARLES M. SCHWAB, or someone acting as his agent, is the likeliest guess.

Essential Qualifications for Commercial Agents in Latin-America

THERE came to us lately a request to recommend a competent man to travel in certain Latin-American countries with a view to securing information as to the needs of industrial establishments located in those regions. It was required of him that he be conversant with the language of the countries in question, and that he shall "know how to comport himself so as to gain the consideration and confidence" of the persons that he meets, in addition to having a broad understanding of a considerable list of manufacturing processes.

Now it is not difficult to find intelligent men who are familiar with the technical demands of such a position. But when it comes to finding such a man who is conversant with Spanish or Portuguese it becomes difficult. And when it is still further required that he "know how to comport himself so as to gain the consideration and confidence" of Spanish-American men of substance, the difficulty becomes greater still. This is not said in any sense of criticism of American technologists; it is merely a statement of fact based upon more or less local habits of life.

The white population of Central America and parts of South America is but a small minority and yet it is generally in control of the greatest business organizations. White domination such as prevails in our own Southern States is out of the question. For this very reason the white minority feels called upon to maintain habits of grace which are more or less traditional. It is demanded, for instance, as an index of good breeding, that everyone speak French with reasonable fluency. A certain familiarity with *belles lettres* and at least with classic art is expected. More or less ancient conventions

are kept up. The obligation of good manners becomes a family tradition. They have what actors call "the grand manner." To those who are unaccustomed to it, it seems affected; but this, after all, is a matter of taste, and everybody, everywhere, is sensitive to criticism of his taste.

Now, many of our technical schools are so intensely practical that graduates often are not even on terms of amity with their own mother tongue, and those studies known as the humanities are passed by as useless. Modern languages also are neglected. Unusual dignity of bearing is frowned upon as lacking in democracy—and very possibly it is. What our South American cousins seek to demonstrate by the grand manner is not democracy; on the contrary, it is the outward and visible sign of their deference to ancient tradition.

The position of the South American person of circumstance, when a man from North America visits him, is that he would like to "get a line on him," as we say; to find out what sort of person he is. He may or may not know the name of the firm represented; the chances are, at all events, that he knows very little about it. The man who calls is his point of contact. If the latter makes a disagreeable impression he does not want any dealings with him. His business relations he also considers as social affiliations—which often confuses the man from the north. Agreeable persons from abroad are scarce, and they are greatly desired. He wants to deal with somebody who can understand him and his ways, including his likes and dislikes. Things that are negligible to the North American buyer become of leading importance to buyers from South America. Dates of shipment, metric units in packages, the size and shape of single packages, and many other details present themselves as more important even than the price to be paid—with in reasonable limitations. There are a thousand reasons why his unbidden visitor should be to him what he terms *simpatica*.

Again, if anything is thrown at a South American buyer with the statement that he can take it or leave it alone, the chances are preponderant that he will leave it alone. If the visitor lacks the time, or the inclination, or the wit, or the understanding to engage in a couple of hours of conversation, the host is unlikely to be interested in anything he has to say. He will be interested, however, the following week if a competitor who knows how to talk to him comes around. He is not ready to discuss business until he has had a chance to size up his visitor.

But suppose the Latin-American prospective buyer to be half or whole Indian, or suppose him to be tintured by a strain of African—suppose him to be a man who

does not even own a white collar; he will nevertheless set himself up to be a person of circumstance; he will assume that his tastes are similar to those of his white fellow citizens; and he also wants to size up his visitor before negotiations begin. He must know beforehand whether the prospective business connector can think as he does.

For the man who goes to South America to do business, a term at a commercial high school and a course in engineering are not enough. What he needs is polish, *savoir faire*, versatility and at least the semblance of grace. Then he can gain the friendship of the real men of substance and get their trade as well. And he can't get any trade worth seeking if he is a roughneck.

Pyrometers for Brass And Bronze Makers

TEMPERATURE control at various steps in brass and bronze manufacture is generally recognized as being most desirable, since it has been clearly demonstrated that intelligent melting reduces metal losses and heat consumption on the one hand and on the other promotes uniformity in the finished work. With the best will in the world, however, a logical application of present knowledge is difficult because durable pyrometers at once rugged and cheap are still unavailable.

Pyrometers would be very useful to give temperatures of metal in a furnace, and in the ladle; the one stationary, the other portable; both must be rugged. Furnace pyrometers would hardly pay except in furnaces of large capacity, especially if adequate portable indicators for metal in ladle were available. Apparently the most feasible furnace control known at present could be had by a gas-tight tube of graphite or some material which does not crack, dissolve or oxidize readily, this tube being raised during the charging and melting stages, then lowered into the bath and observed by an optical instrument. Such a device could be made extremely rugged, since there is plenty of time to overcome the lag due to heat capacity. It must be made of insoluble materials, however, since it must be arranged so it can be plunged into the metal—a tube in the furnace walls or anywhere else is worthless. Its use undoubtedly would save time and fuel, while giving minimum oxidation and absorption of gas.

Fortunately, modern electric-furnace design with its attendant greater control over temperature will reduce the need for a furnace pyrometer. Thus, on 24-hour operation a given number of kilowatts applied to a given charge for a given time will produce metal of the same temperature on successive heats, while on intermittent operation, the needed power input for each heat can be scheduled.

The second need, which will exist even when the first is solved, is for an instrument which will read temperatures in the furnace just before pouring or in the ladle. Here one must have not only speed but accuracy as well. One minute per ladle amounts to many hours per month; and one cannot wait long when deciding whether metal is just hot enough to pour certain castings without a misrun.

Speed means thermo-elements with small mass, which in turn eliminates refractory non-metallic protection tubes rugged enough to remain long in a foundry. Bare, base-metal couples will give speed, but practically all present analyses are rapidly corroded, and the readings are accurate only when the metal has an absolutely clean

surface and is thoroughly mixed at the instant, since all the immersed portion is short-circuited and it is the temperature of the surface which is indicated. If there is a layer of slag, charcoal or oxide on the metal, the readings are scarcely more dependable than a judgment by eye—optical pyrometry clearly being inadequate.

Speed and accuracy call for metallic tubes of small mass—preferably of an insoluble alloy which could form one leg of the circuit, like the iron tube of the iron-constantan couple so satisfactory for aluminum. The choice of metal is not easy—in fact, it has occupied the attention of the Bureau of Mines alloy chemists for some time. It must have proper thermo-electric properties, it must not be brittle, it must be stiff and strong, it must be insoluble in hot alloys, and be capable of being drawn, cast or welded into thin-walled tubes. Nickel, either pure or alloyed, is very soluble; iron much less so. Pure chromium, molybdenum and tungsten are almost insoluble, but ductile molybdenum and tungsten oxidize just above working temperatures and are very expensive and hard to procure. A perfect chromium plating on a nickel tube would serve excellently, but a single pin hole or scratch ruins the tube. An alloy of 25 per cent chromium, 75 per cent iron, can be cast into moderately thin-walled tubes, but corrodes in rather an erratic manner. Heavy tubes of an iron-chromium analysis have been rather extensively used, but to cut down lag they must be constantly kept at about 1000 deg. C. in a separate furnace of small dimension.

Thus the metallic tube seems to be the crux of the problem—suitable couples and meters are now known. For standardization and experimental work quartz protection tubes were satisfactorily used by the Bureau of Standards, while Dr. GILLET recommends a nickel tube protected by silfrax and tipped with a bare molybdenum nipple. Either of these has its obvious disadvantages and limitations when applied to work on the foundry floor and it is hoped that future research will bring to a successful end the large amount of admirable work already done on the problem of rugged pyrometers for use in brass and bronze. Eventually an insoluble dense alloy which can be drawn or rolled into tubes, or machined into closed end tubes of thin wall section will doubtless be found.

Declaration of American Policy Toward German Dyes

AT THE recommendation of the Advisory Committee on Dyes, the War Trade Board Section of the Department of State has issued a public statement of the policy underlying the present temporary control which is being exercised over the importation of German dyestuffs. On July 26 it was announced that, for the present, no licenses whatsoever are being issued for the importation of any dyestuffs produced or manufactured in Germany. The adoption of a permanent policy affecting the importation of dyestuffs is now being considered by Congress.

Licenses are being issued freely, however, for the importation of all dyestuffs produced or manufactured in non-enemy countries, especially Great Britain and Switzerland. Furthermore, under the provisions of Annex VI of Part VIII of the Treaty of Peace with Germany, which is printed on another page in this issue, German dyestuffs will become immediately available to American consumers under certain restrictions when the treaty comes into effect. Quantities will only

be such as are necessary to meet domestic requirements, and prices will be fixed by the Reparation Commission. Nevertheless, as the result of a careful survey of the present situation in the dye-consuming industries and the unanimous opinion of the Advisory Committee on Dyes, there appears to be no such need for German dyestuffs in the United States as to warrant the issuance of licenses for their importation.

An earlier announcement of the War Trade Board Section on July 20 explained that vegetable dyes of natural origin may be imported without individual license.

The Shoe on The Other Foot

THE War Department announces that it is offering its surplus stock of platinum for sale at a minimum price of \$105 per ounce. Purchasers may buy not less than 10 ounces or more than 1000 unless the Director of Sales deems it advisable to grant special permission for a sale of larger quantity. Incidentally we note that the Director of Sales has studied the market and method of disposition and has come to the conclusion that the scheme proposed will, as he says, "assure the Government the highest return for its surplus stock and at the same time prove most beneficial to the general public."

Without any intention of being uncharitable or cynical we cannot help recalling the situation of about a year ago when the War Industries Board arbitrarily set a price of only \$90 per ounce on the platinum it confiscated, despite the fact that the market price for over a year and a half previous had been \$105. Can it be that insult is now to be added to injury by offering back, to those from whom it was taken, the same metal at an advance of \$15 per ounce? We fully recognize the fact that the present Director of Sales is not the War Industries Board; also that each may plead zeal in the Government's cause. Beyond that it seems evident that the patriotic citizen is asked to demonstrate the quality of his loyalty to the extent of taking a loss at both ends of the line.

Steel Production During the War

PRODUCTION of steel ingots and castings, in gross tons, has been as follows, beginning with the two pre-war years, easily the largest tonnage years in the industry before the war:

	Ingots	Castings	Total
1912	30,284,682	966,621	31,251,303
1913	30,380,130	1,020,744	31,400,874
1914	22,819,784	693,246	23,513,030
1915	31,284,212	866,824	32,151,036
1916	41,401,917	1,371,763	42,773,680
1917	43,619,200	1,441,407	45,060,607
1918	43,051,622	1,411,410	44,463,032

There was full operation of the steel industry from the late spring of 1912 until the late fall of 1913, and it was merely a coincidence that the ingot tonnages of the two years were almost precisely the same. There was some increase in capacity during the two years. There was no further increase in capacity until the latter part of 1915, while thereafter capacity increased rapidly, as to the making of steel, and as this increase was called for because of the demand for shell steel there was little tendency to increase finishing capacity, except in the one case of plates.

From a consideration of various details it may be

estimated that capacity in steel ingots was about 35,000,000 tons in 1914 and is now about 49,000,000 tons, which would show a war-time increase of precisely 40 per cent. With production in 1912 and 1913 at less than the capacity at the end of 1913, and with production in 1918 interfered with by insufficiency of rail transportation, affecting in particular the supply of coke, and with other difficulties, it chances that the gain in production from 1912-13 to 1918 was 42 per cent, or almost precisely the same as the estimated increase in capacity from 1914 to the present time. In the production of steel castings there was approximately the same gain.

The production of rolled iron and steel in gross tons is shown in the table below. The system used in compiling the statistics is to take the material in its form after its last hot rolling (of course after shearing), whereby billets, sheet bars, etc., are not counted except when they are exported, and then of course they are counted at their weight when exported; rods are counted rather than rod billets or drawn wire, skelp is counted rather than pipe, black plate rather than tin plate, and so on.

	Rolled Steel	Rolled Iron	Total Rolled
1912	23,019,259	1,637,582	24,656,841
1913	23,112,986	1,678,257	24,791,243
1914	17,202,420	1,167,776	18,370,196
1915	23,098,091	1,294,833	24,392,924
1916	30,557,818	1,822,571	32,380,389
1917	31,199,943	1,867,257	33,067,200
1918	29,581,778	1,571,976	31,153,754

The increase in rolled steel production from 1912-13 to 1918 was 28 per cent, or much less than the 42 per cent shown for ingots. That, of course, reflects the large production of shell steel in 1918, with heavy cropping of the ingots. Evidently not as much was accomplished as was hoped for by the War Industries Board, in finding rolling uses for shell discard steel. Apparently the great bulk of the material became scrap, or else there was a large stock of ingots at the close of the year, for the proportion of rolled steel to ingots in 1918 was 69 per cent, against a normal of 76 per cent in 1912 and 1913.

The production of rolled iron decreased sharply in 1918 as compared with either of the two preceding years, while the production of ingots was much the same in the three years. The decrease in rolled iron was probably due in part to shortage of scrap, but in part also it was presumably due to lightness of demand. The strictly war demand ran almost entirely to steel, and the railroads did not buy as much, either iron or steel, as in previous years. The 1918 rail production, for instance, was only 2,540,892 tons, or about 350,000 tons below the average of 1916-17 and 850,000 tons below the average of 1912-13, yet a large tonnage of rails went abroad in 1918.

The production of sheared plates, 4-inch and heavier, amounted to 3,145,284 tons, against a production of 1,432,254 tons in 1913, showing an increase of 2,013,030 tons, or 140 per cent. A negligible tonnage of iron plates is included in the figures mentioned. As several of the new plate mills were not completed until late in 1918, the existing capacity is considerably greater than the production shown for 1918. No new plate mills will be needed for a long time.

The steel industry easily made good its promise in May, 1917, that the country would not be under the necessity of building wooden ships through inability to obtain steel plates.

Readers' Views and Comments

Flakes in Nickel Steel Gun Forgings

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the Rochester district during the past two years the Ordnance Inspection Office had considerable trouble with flakes in gun forgings made in that region.

Recently we reviewed all reports of physical tests on guns and classified the data contained. The results are especially interesting in that they compile the tests on approximately 4000 gun forgings in this summary.

Chart No. 1 shows that in forgings made from ingots cast during the months of January, February and March, 1918, over 50 per cent contained flakes. The percentage of flakes decreased continually after Feb-

CHART 1.

Curve showing per cent of "flaky" forgings received from one steel plant. Date of casting used in classification. Figures based on results of 3500 forgings.

ruary, and the forgings that were cast in September, October and November showed no signs of this flaw.

Chart No. 2 shows how the percentage of flakes varies with the nickel content. It will be noted that the tenderness of nickel steel and the tendency to flake

CHART 2.

All forgings with Ni content from 1.75 to 2.25 were grouped together in 2 per cent class. Per cent "flaky" obtained by dividing total showing flake by total in class. Same procedure followed to obtain per cents at 2.5-3.0-3.5 Ni. Figures based on average of 3000 forgings.

increases quite rapidly with the nickel content up to 3 per cent.

Practically all the forgings produced during January,

February and March, 1918, contained 3 to 3.5 per cent nickel. After that time the percentage of Ni was decreased until the forging ingots cast in September, October and November, 1918, were made of either straight carbon steel or steel containing 1 per cent of nickel. A great deal more care was also taken in casting and forging as the seriousness of this flaw was realized.

Dr. H. M. Howe's theory of cracks forming either when the ingot is cooling or when it is forged seems very logical to me. The physical results obtained from test bars seemed the only argument against it. To settle this point in my own mind, I carefully measured the area of several flakes in different bars and subtracted

TABLE I.

Physical Properties Based on Full Area				Physical Properties Full Area Minus Area of Flake	
Ultimate	El. Limit	Per Cent Elong.	Per Cent Red.	Ultimate	El. Limit
87,100	58,300	5.5	14.1	100,500	67,200
60,300	50,000	2.0	7.1	120,600	
83,900	54,000	7.5	22.3	103,600	67,800
62,500		Double fracture		109,500	
73,900	54,800	5.5	10.0	98,500	73,000
94,000	65,000	3.5	9.3	134,000	92,250
84,800	64,000	3.0	10.4	105,000	79,500
94,900	65,000	6.5	17.6	111,500	76,500
76,100	60,000	3.5	16.8	99,500	78,500
86,200	68,000	3.0	14.5	109,000	84,000
83,400	61,800	4.0	11.2	103,000	76,300
81,000	64,000	3.0	3.5	108,000	85,500
79,300	53,100	4.5	10.2	91,000	61,000
81,400	60,000	3.0	8.1	97,000	71,500
73,500	56,000	2.0	5.1	92,000	70,000

this area from the original area of the bar. The figure thus obtained was the actual area of sound metal. I then divided this area into the load at elastic limit and tensile strength. It is to be noted that the tensile strength obtained in this way is not unreasonable in any case. Table I gives the figures for several bars.

I feel that this trouble was due entirely to forced production and that it will disappear entirely now that the need of steel is not so great and more care can be taken in making the steel correctly. Flakes tended to form by heats. However, this was not always the case. Results indicate that the tenderness of the steel is dependent on the conditions under which the steel is made and thus varies from different heats.

RALPH A. HAYWARD.

District Metallurgist,
Rochester Ordnance Office,
Rochester, N. Y.

Electric Brass Melting

To the Editor of Chemical & Metallurgical Engineering

SIR:—May I direct your attention to an error appearing in your issue for July 1, 1919, page 9, wherein you give the power cost for an electric furnace as 0.86 cent per kilowatt-hour. This figure would be correct if all of the 70,000 kw.-hr. used per month was charged to the electric furnaces; but as a matter of fact 20,000 kw.-hr. was used for lights or motors, leaving only 50,000 used directly by the furnace. Accordingly, the equation at the bottom of page 9 should be $602.5 \div 50,000 = 1.205$; also the first line on the top of page 10 should read "The electric furnace cost is 1.205 cents per kw.-hr., and in Table II. p. 10, the power price for the first case is 1.205 cents instead of 0.860.

New York City.

Western Chemical and Metallurgical Field

Low-Temperature Distillation

A PROCESS for low-temperature carbonization which has attracted more or less notice in British Columbia has been experimented with at Nanaimo under the auspices of the inventor, Walter Thomas, and a Vancouver firm, McPherson & Fullerton Bros. Originally it was tried on Nicola Valley coal; the products were a semi-coked smokeless fuel, and about 7 gal. of oil per ton of fuel, with little permanent gas. Later work has produced a good dense charcoal from mill waste obtainable for a few cents per cord. In operation, a vertical brick-lined retort some 14 ft. high and 3½ ft. in diameter is filled with coarse material to be carbonized, then closed, and the air contained in the system forced by a fan through a pipe stove and into the top of the retort. This passes down through the mass to be carbonized, thence through a pipe condenser and an electrical precipitator to remove liquid hydrocarbons, and back to the fan for recirculation. As the carbonized fuel becomes hotter, gases will be given off so that after a time rich distillation gas should constitute the circulating medium.

Dr. Stansfield in his recent report on Electric Smelting of Iron Ore in British Columbia presents a short note on this process. He sees many drawbacks to the scheme as it was illustrated to him, such as the difficulty of forcing gas through the field retort, the slow heating of the carbonizing mass by the circulating gases, which are of low temperature and low heat capacity, the inefficiency and expense of the ordinary pipe stove, and the decomposition of hydrocarbon which will take place at this point. He has been assured, however, that enough work has been done to convince the backers of the process that they can make satisfactory charcoal at a cost of about \$5 per ton, in a cycle of operations lasting six hours.

Magnesite for Flooring Composition

Magnesite trade has been generally very quiet since the signing of the armistice, marking time with the steel industry, the principal consumer. Refractory manufacturers absorb perhaps 85 per cent of the magnesite output in making brick and granular material for steel and copper furnaces, while the balance is used chiefly for flooring. For the latter, both caustic magnesite (carbonate burned down to 2 to 4 per cent CO₂) and a German magnesite chloride were used before the war. Recently, however, a scarcity of materials has raised the price of high-grade floor compositions to a point where their use is almost prohibitive.

The principal manufacturers of composition flooring have lately organized and instituted a co-operative research at the Pittsburgh laboratory of the Bureau of Standards to determine proper specifications for raw materials, calcination and method of laying the floor. It is hoped that the price can be brought into competition with that of hardwood flooring, when large quantities of it should be used.

As is well known, the principal American deposit is in Washington, where large-scale production is possible under most favorable manufacturing conditions. California deposits are more scattered and not well developed, and will consequently produce but little low-

cost material. Argenteuil County, Quebec, has notable magnesite resources, having shipped 16,700 tons crude ore, and 22,700 tons of calcined material during 1918, of which 80 per cent was exported, mostly to the United States.

Iron and Steel in Canada in 1918

Canada produced 1,163,520 short tons of pig iron in 1918 from blast-furnaces, including those of the Dominion Iron & Steel Co., at Sydney, N. S.; the Nova Scotia Steel & Coal Co., at North Sydney, N. S.; the Standard Iron Co., at Deseronto, Ont.; the Steel Company of Canada, at Hamilton, Ont.; the Canadian Furnace Co., at Port Colborne, Ont., the Algoma Steel Corp., Ltd., at Sault Ste. Marie, Ont., and the Midland Iron & Steel Co., at Midland, Ont. This production was slightly less than in the two years preceding, but it was augmented by 30,425 tons of electric pig from steel scrap, mostly low-phosphorus pig from shell turnings. Such electric furnaces were operated at Hull and Shawinigan Falls, Que., at Orillia, Collingwood, St. Catharines, Toronto, Belleville, and Bowmanville, Ont., and at Port Moody, B. C. Ferros, chiefly ferrosilicon and a little ferromolybdenum and ferrophosphorus were made in electric furnaces to the extent of 44,700 tons, valued at \$4,730,000, over half of which was exported. Practically all the pig iron was consumed in Canada, however, the amount being slightly increased by a net import of about 65,000 tons.

Steel ingots and direct steel castings amounted to 1,893,000 short tons, of which 73,000 tons were of the latter category. Both of these classifications show a considerable increase over the figures for 1917. Electric steel amounted to 120,000 tons, as compared with 50,000 in 1917 and 61 in 1914. Some 220,000 tons of steel products (exclusive of shell) were exported. Thus Canada is practically self-contained as to iron and steel products of ordinary use.

Electrometallurgical Research Laboratory in San Francisco

A laboratory designed to investigate problems arising in the electric smelting of various kinds of non-ferrous ores has been added to the laboratories of the Beckman & Linden Engineering Corporation at San Francisco, and is now working on a nickel-copper ore which apparently will give a metal of similar character to monel metal. In view of the variety of mineral resources of the West Coast and the large amounts of hydro-electric power which will be available in years to come, the laboratory should prove to be of great help in promoting electrothermic reduction of ores in that region.

The equipment consists of complete electrical appliances to give 100-kw. single-phase current at a voltage range of from 40 to 120, together with proper switch-board and portable instruments for studying the electrical and temperature conditions during operation of a furnace. Semi-permanent furnaces will be erected as required by the study in hand, as is usual in research laboratories of this sort, an ample supply of leads, electrodes, refractories, ladles, molds, sampling equipment, and so on, being held in stock. In addition to this equipment, the laboratory is equipped with a 15-kw. low-voltage motor generator set, with the necessary accessories for studying problems in electrolytic decomposition and deposition.

Tapping-Floor Ventilators

"Safety-first" movements are responsible for the almost universal installation of ventilating hoods over forehearths and ladles around lead furnaces, for removing smoke perhaps more annoying than dangerous except at the lead well. Some of the installations work but passably, and tempt the furnaceman to neglect them, since they remove so little smoke as to be worth little trouble. He feels that he should not be asked to do anything except keep the lower part of the furnace in operating order, and such extra frills must be practically foolproof and automatic if they are to remain in operation. Even in the best installations which keep the tapping floor practically free from

SKETCH OF HOOD SYSTEM FOR LEAD FURNACE

smoke, it is almost impossible to get workmen to close a damper in the matte-pan hood during the time it is not needed and thus save draft; if, on the other hand, stoppage of the fan throws the entire system out of order, they pour out of the building and vociferously demand more speed in repairing a condition they would have accepted as part of the job ten years ago.

Herewith are sketched some ideas observed in a successful hood system at a furnace using two forehearths in series. Since these crust over with chilled slag soon after being replaced, it is only necessary to hood the spouts and a small area where the slag enters. Furnacemen will keep these hoods somewhat high so that the outer air drawn in around the cages will not burn too quickly the wood placed on the spouts to keep them open, so extra clearance should be allowed at these places. One side of the hood at the furnace should also be cut back as shown, so that the tap-hole may be opened and closed without continual adjustment.

A complete system will involve hoods closely covering the lead pot, the matte pan and the slag pot, as well as two for the spouts to settlers No. 1 and No. 2. Each is closely counterweighted so it can be easily raised out of the way, by a rugged mechanism somewhat like that indicated, the lower pipe, smooth outside, telescoping into the upper part through a flap of conveyor belting, simple stops limiting the travel. Shaft A, for instance, is extended a sufficient distance to carry a guarded sprocket so that a loop of light chain can hang down to a handy point on the floor, easily reached and yet not interfering with ordinary furnace work. A like arrangement actuates a butterfly valve in each pipe, its

position, whether open or shut, being shown by an arrow at the side of the pipe.

Exhaustion is effected by a fan capable of handling 6000 cu.ft. per min. per furnace; a draft of about $1\frac{1}{2}$ in. at the fan will usually be sufficient. The very dilute smoke is discharged into the main blast-furnace flue, and the values recovered. As noted before, the fume rising from the lead pot is dangerous, the dense sulphur fumes from the matte pan quite irritating, while the mixed smoke from a slag stream is disagreeable from its volume and heat.

Exposition Plans and Exhibitors

THE Fifth National Exposition of Chemical Industries, which will be held in Chicago during the week of Sept. 22, promises to be of exceptional interest, since many of the inventions and developments made under the stress of war-time necessity will be shown publicly for the first time. As instances, we may mention: acid and alkali proof bronzes, prepared for specific purposes that even quite recently were unheard of; bronze of such hardness and strength that instruments made of it are used to cut chilled steel; technical organic products developed for waterproofing and fireproofing; instruments perfected during the war for precise measurements of temperatures, weights, volumes, velocities, flow of liquids, gases, electric currents, etc.

A feature of the exposition will be the exhibits of electric furnaces, which will include the Rennerfelt furnace, handled in America by Hamilton & Hansell; the Bailey furnace, by the Electric Furnace Co.; the Taylor furnace, by the Industrial Electric Furnace Co.; the Detroit Rocking furnace, by the Detroit Electric Furnace Co., the furnace of the Booth-Hall Co., and many others.

The Bureau of Mines will show the complete course of extraction of some thirty metals from their ores, together with the materials used in the extraction. In addition, the Bureau will have a collection of protective and safety devices, such as goggles, shields, masks, hoods, oxygen helmets, etc., and will hold a symposium upon "Safety in the Plant and Mine," with speakers of authority in this work, under the chairmanship of M. L. Leopold, safety engineer of the U. S. Bureau of Mines. In the evening after this meeting, which will occupy an entire afternoon, there will be shown a series of motion pictures of safety work in plant, field and mine—pictures now being made in industrial plants all over the country under the supervision of Government agents.

The Forest Products Laboratory of the Forest Service will make an exhibit of the work it has been conducting on processes, raw material, products, by-products, etc. Among the subjects will be the investigation on pulp and paper, ethyl alcohol from wood waste and sulphite liquor, the increased production of acetate of lime in hardwood distillation, and the naval stores investigations.

The Technical Association of Pulp and Paper Industry is planning an exhibit showing all the phases and stages in paper making from the tree to the finished paper, including illustrations of the machinery through which pulp passes in all stages.

The Bray Studios will endeavor to show, by means of animated drawings, the mechanism of certain chemical actions usually invisible to the eye and only conceived

by the mind in abstract form. The following partial list of exhibitors indicates clearly the scope of the Exposition:

Abbe, Paul O.

Status of the Domestic Magnesite Industry

AT A tariff hearing before the House Ways and Means Committee on June 16 and 17, 1919, it was testified that before the war 95 per cent of the magnesite consumed in this country was imported from Austria and that since then most of it has been produced from mines located in California and in Washington State.

In 1914 the cost of imported dead-burned magnesite at Atlantic ports was between \$16 and \$17 a short ton, and the brick made from this material sold for \$112 a thousand, 9-in. standard basis. The cost of dead-burned domestic magnesite, at the time of the hearing, at Atlantic ports was \$19.10, and brick made from this material was bought for \$400 a thousand. As much as \$600 a thousand was paid during the war.

The amounts imported are shown in Table I and the domestic production in Table II.

The domestic magnesite is procured from deposits in California, where it occurs in an amorphous form in veins of varying size, and from deposits in Washington State, where it occurs in a crystalline form in large massive deposits similar to limestone. The development of the California deposits is shown in Table III. The Washington deposits were not developed until 1917. During the year 1918 two companies produced 105,175 short tons crude magnesite from the deposits located at Chewelah and Valley. The known reserves in this country are 8,000,000 tons, the deposits of southern Europe are estimated to contain between 120,000,000 and 130,000,000 tons.

The request of the producers for a protective tariff is incorporated in bill H. R. 5218 as follows:

A BILL To provide revenue for the Government and to establish and maintain the production of magnesite and manufactures thereof in the United States.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That on and after the day following the passage of this act, there shall be levied, collected and

paid upon the articles named herein, when imported from any foreign country into the United States or into any of its possessions, the rates of duties which are herein prescribed, namely:

1. Magnesite, commercial ore, either crushed or ground, three-fourths of a cent per pound.

2. Magnesite, calcined, dead burned and grain, 11 cents per pound.

3. Magnesite brick, 25 per centum ad valorem.

SEC. 2. That paragraph 539 of the tariff act of Oct. 3, 1913, is hereby expressly repealed; and that so much of paragraph 71 of said tariff act and of any heretofore existing law or parts of law as may be inconsistent with this act are hereby repealed.

The testimony of the witnesses at the hearing is conflicting; consumers of brick made from domestic magnesite claimed it to be inferior to brick made from Austrian magnesite, the life of the domestic product being between 60 and 80 per cent of the foreign. H. F. Wierum, general manager of the American Mineral Production Co., at Valley, Wash., claimed that brick made from a dead-burned magnesite produced at his plant was equal to brick made from Austrian magnesite.

TABLE I—IMPORTS OF MAGNESITE CALCINED, NOT PURIFIED, FOR FISCAL YEARS ENDING JUNE 30, 1912-17, BY COUNTRIES, IN SHORT TONS

Country	1912	1913	1914	1915	1916	1917

1901	3,500	10,500	1915	30,499	274,491
1902	2,830	8,490	1916	154,974	1,393,693
1903	3,744	10,595	1917	316,838	2,899,818
1904	2,650	9,298	1918 (estimated)	225,000	

* From Mineral Resources, 1914-17.

TABLE III—CRUDE MAGNESITE PRODUCED IN CALIFORNIA, 1913-17*

Year	Producing Mines	Quantity, Short Tons	Value
1913	1	9,632	\$77,056
1914	6	11,293	124,223
1915	16	30,499	274,491
1916	45	154,259	1,388,331
1917	65	211,663	2,116,630

* From Mineral Resources, 1917.

The difference between the Austrian and the domestic magnesite is principally in the amount of hematite present.

At the Valley plant magnesite and hematite are ground to 200 mesh. After being thoroughly mixed in the proper proportion the mixture is fed into a revolving kiln 165 ft. in length. The temperature in the hot zone of the kiln is 2900 deg. F., which insures perfect fusion; the product is homogeneous. Material manufactured under these conditions has been produced since

March this year, and brick made from this product has been as satisfactory as those made from Austrian magnesite. This plant seems to be the only one that has made an intelligent effort to produce a dead-burned magnesite which will produce a satisfactory brick, and it is probable that co-operation between the producer of dead-burned magnesite and the manufacturers of brick will lead to more satisfactory results.

Ways and Means Committee Acts on Tariff Bills

THERE is a safe majority among the members of the Committee on Ways and Means of the House of Representatives opposed to the licensing system. This fact developed at the first meeting of the committee to consider the evidence submitted at the hearings which had been conducted on various commodities which were most in need of safeguarding. The opposition to the licensing system does not extend to that suggested for the dyestuff industry, in which it is practically certain that a licensing plan must supplement the duty.

At its meeting, the committee reported favorably, without amendment, the bill introduced by Representative Timberlake, of Colorado, providing duties on tungsten. The rate of duty on crude tungsten, ores and concentrates, as provided by the bill, is \$10 per unit. Metallic tungsten and the various tungsten products and salts, including manufactured materials containing tungsten, are to pay duty at the rate of \$1 per lb. The vote on the bill was along party lines, with the exception of Representative Martin, of Louisiana, a Democrat, who voted with the Republicans. The Democrats favor the licensing plan, rather than a tariff.

The committee also reported favorably Representative Bacharach's bill providing duties on laboratory glass and porcelain ware, optical glass, scientific and surgical instruments. The rates of duty prescribed under the bill are as follows:

Glasswares and porcelain wares, laboratory apparatus, and other apparatus and appliances wholly or in part of glass or porcelain, for use in the sciences or in analyzing or testing or for use in education, 60 per centum ad valorem.

Optical glass in any and all forms of glass for use in optical instruments or for any optical purposes, and all instruments and appliances of any and all kinds containing parts of optical glass or used for optical purposes, finished or unfinished, 45 per centum ad valorem.

Philosophical, scientific, and laboratory apparatus, utensils, instruments, and appliances and parts thereof, finished or unfinished, and preparations, including bottles and boxes containing the same, not otherwise provided for, 45 per centum ad valorem.

Surgical and dental instruments, or parts thereof, made wholly or in part of iron, steel, copper, brass, nickel, aluminum, or other metal, finished or unfinished, 60 per centum ad valorem.

DYES, POTASH AND MAGNESITE STILL UNDER CONSIDERATION

The committee, at this writing, still has under consideration the dyestuffs bill and the potash bill, as well as that providing a duty on imports of magnesite. It is believed that the committee is likely to report out substantially the revised Longworth dye bill. In addition to specifying a free list and providing a rate of tariff for the dutiable list, the bill provides for a dye licensing commission as outlined in our issue for July 15, p. 65. The commission shall issue licenses for such dyes as may be unobtainable from domestic sources and shall limit importations as nearly as possible to quantities required by current needs in the United States.

One of the developments of the situation is that the Tariff Commission is very much opposed to administering any licensing system. It came to the ears of the Commission that it had been suggested as the proper body to administer the licensing machinery, and the result was that the Commission not only reiterated its opposition to most of the licensing suggestions, but emphatically urged that it not be selected to administer any of the licenses.

Dr. Hoyt S. Gale of the Geological Survey, in testifying this week before the House Ways and Means Committee, said that the German potash industry could not regain the position it held before the war. The increased cost of labor and the internal condition of the industry, he said, were such that German potash would have to sell for at least \$1.50 per unit.

Dr. Gale returned to Washington last week from Europe, where he made a study of the potash industry, and it was at the special request of Secretary Lane that the Ways and Means Committee summoned him to testify.

W. E. Sharp, president of the Western Potash Works and of the American Potash Co. of Lincoln, Neb., denied to the Committee that the potash industry of this country was controlled by the packers. He admitted, however, that one company was owned by the packers, but said that the products of that company were used by the owners in the manufacture of fertilizer.

The hearings on potash and dyestuffs before the House Ways and Means Committee will not be resumed until after the House recess, Sept. 8.

International Exposition of Mining Industries

A permanent exhibit of mining and metallurgical machinery is to be established under the direction of the Merchants and Manufacturers Exchange of New York, which has taken over Grand Central Palace for the purpose of maintaining industrial exhibits of various kinds. Approximately 50,000 sq.ft. of space, or one entire floor, will be devoted to the machinery and supplies used in the development and operation of metal mines, non-metal mines, coal mines and oil wells; subsequent extraction or refining of the raw products by concentration, leaching, cyaniding, flotation, smelting, distillation, coking, etc.

The new enterprise enjoys unusual support in the backing of the Nemours Trading Corporation, of which Alfred I. duPont is president. The corporation owns and controls the Merchants and Manufacturers Exchange of New York and has branches in the leading cities of the world consisting of 19 branch offices and 3000 foreign selling agents. The purpose and function of the venture are to develop both foreign and domestic trade in all lines of industry and to establish at a central point a permanent exhibit of machinery and products for the benefit of foreign and domestic merchants.

The exhibit of mining industries will include aerial and surface transportation, laboratory appliances and supplies, blast-furnaces and other ore-treating equipment, compressors, crushers, concentrating machinery, hoists, drills, power machinery, ventilating equipment, etc. The exhibition will be under the direct management of Mr. Howard R. Ward, a mining engineer who prior to entering war work was for three years consult-

ing mining engineer for the American International Corporation. The present headquarters of the International Exposition of Mining Industries is Room 421, 405 Lexington Ave., New York.

Peace Treaty Provisions Regarding German Dyes and Chemicals

The War Trade Board Section of the Department of State quotes, for the information of those concerned, the following provisions of the Treaty of Peace relative to German dyes and chemicals:

ANNEX VI

1. Germany accords to the Reparation Commission an option to require as part of reparation the delivery by Germany of such quantities and kinds of dyestuffs and chemical drugs as the Commission may designate, not exceeding 50 per cent of the total stock of each and every kind of dyestuff and chemical drug in Germany or under German control at the date of the coming into force of the Treaty.

This option shall be exercised within sixty days of the receipt by the Commission of such particulars as to stocks as may be considered necessary by the Commission.

2. Germany further accords to the Reparation Commission an option to require delivery during the period from the date of the coming into force of the present Treaty until Jan. 1, 1920, and during each period of six months thereafter until Jan. 1, 1925, of any specified kind of dyestuff and chemical drug up to an amount not exceeding 25 per cent of the German production of such dyestuffs and chemical drugs during the previous six months period. If, in any case the production during such previous six months was, in the opinion of the Commission, less than normal, the amount required may be 25 per cent of the normal production.

Such option shall be exercised within four weeks after the receipt of such particulars as to production and in such form as may be considered necessary by the Commission; these particulars shall be furnished by the German Government immediately after the expiration of each six months period.

3. For dyestuffs and chemical drugs delivered under paragraph 1, the price shall be fixed by the Commission, having regard to pre-war net export prices and to subsequent increases of cost.

For dyestuffs and chemical drugs delivered under paragraph 2, the price shall be fixed by the Commission, having regard to pre-war net export prices and subsequent variations of cost, or the lowest net selling price of similar dyestuffs and chemical drugs to any other purchaser.

4. All details, including mode and times of exercising the options, and making delivery, and all other questions arising under this agreement shall be determined by the Reparation Commission; the German Government will furnish to the Commission all necessary information and other assistance which it may require.

5. The above expression "dyestuffs and chemical drugs" includes all synthetic dyes and drugs and intermediate or other products used in connection with dyeing, so far as they are manufactured for sale. The present arrangement shall also apply to cinchona bark and salts of quinine.

German-Owned Chemical Plants Sold

The largest single day's sale of German-owned property was made at public auction on July 18 by the Alien Property Custodian. The sale of three chemical plants brought \$1,419,980. The successful bidders were W. E. Coffin & Co. and the American Aniline Products, Inc., of 80 Fifth Ave., New York.

The Roessler & Hasslacher Chemical Co., of 100 William Street, New York City, with plants at Perth Amboy, N. J., and St. Albans, W. Va., was bought in at \$565 a share. The stock of the Niagara Electro Chemical Co. sold at \$3000 a share, the total price being \$140,000. The concern has offices at 100 William Street, New York, and plants at Perth Amboy, N. J., and Niagara Falls, N. Y. The Perth Amboy Chemical Co. stock went for \$940,800, or \$480 a share.

FIG. 1. GENERAL VIEW OF PLANT OF MINNESOTA BY-PRODUCT COKE CO., ST. PAUL, MINN.

From the left are: Coal crushing tower, stack, housing for inclined coal conveyor from coal dumping building in center foreground to top of the coal crushing tower, housing for inclined coal conveyor from bottom of coal crushing tower to top of coal storage bins at end of Battery B, from which bins the larry car is loaded with coal to be charged into the ovens. In the left-hand background are the two batteries totaling 65 ovens. To right of battery storage bins in order are: By-product buildings, rich and lean gas holders, final gas coolers and light oil scrubbers.

The Coking of Illinois Coal in Koppers Type Oven*

An Operating Test at the St. Paul Plant of Minnesota By-Product Coke Company Conducted Jointly by the National Bureau of Standards and the United States Bureau of Mines for Coking Orient, Franklin County, Ill., Coal

By R. S. McBRIDE† and W. A. SELVIG‡

THE great importance during the war period of substituting Mid-Continent coal for coals from more distant sources even in by-product coke-oven work was well recognized. The Bureau of Standards was ordered to conduct an investigation of a new coke-oven process claimed to be especially suited to this purpose, and in connection with this the Bureau was requested to conduct a test of the St. Paul plant of the Minnesota By-Product Coke Co., which is owned by the Koppers Co., Pittsburgh. The Bureau of Standards, in co-operation with the Bureau of Mines, carried out this operating test, using during 7½ days about 7700 tons of coal from the Orient Mine, Franklin County, Illinois.

The plant is usually operated with a mixture of Pittsburgh, Elkhorn and Pocahontas coal at normal coking times of about 16 and 17 hr. The normal capacity of the plant is approximately 1100 tons of coal per day. For the test period only Orient coal was used. Since the coking time for this coal was slightly longer than for the usual mixture, the capacity of the plant was reduced somewhat.

All phases of coal handling, by-product recovery and laboratory tests were under observation by the staff of

37 Government engineers and chemists employed on the work. In addition, those in charge had the benefit of advice and comment from a considerable number of experts who are specialists in the field of coke-oven operation. The quantity of all coal used and of all by-products obtained was carefully weighed or measured at regular intervals and samples of each material were taken for analysis. The Bureau of Standards was responsible for the general planning and supervision of the test work. Its representatives made all observations of battery operation, high temperature measurements, by-product recovery, and chemical laboratory work on gas and by-products. The Bureau of Mines was responsible for the sampling of the coal both as it was loaded at the mine and as crushed at the plant. It supervised the weighing, coal-handling, coke-handling and coke-sampling operations and made all analyses of coal and coke. Its representatives also made general observations on the character of the coke and operation of the ovens.

The Minnesota By-Product Coke Company plant consisted of 65 ovens, built with a gross regenerative system, operating during the test period with an average gross coking time of 19 hr. and 33 min., with coal finely pulverized, 12.75 tons per oven as charged. Each oven was 39½ ft. long, 9½ ft. high, 17 in. wide at the pusher side and 19½ in. at the coke side, making a 2½-in. taper with an average width of 18½ in. The coke was

*This is an advance publication in abbreviated form of Bureau of Standards Technologic Paper No. 137. Published by permission of the Directors, Bureau of Standards and Bureau of Mines.

†Engineer chemist, Bureau of Standards.

‡Assistant chemist, Bureau of Mines.

FIG. 2. GENERAL VIEW OF PLANT (CONTINUED)

In the foreground from left to right are shown: Coke wharf, housings for the coke conveyors, the first screening station where large furnace coke is separated from run of oven coke, and the housing for the inclined coke conveyor to final screening station, where the coke is further separated into small furnace and domestic sizes. In the background are the final gas coolers and light oil scrubbers, shown also in Fig. 1, the power plant, laboratory, complete light oil refining buildings, and coke-quenching station.

discharged from the ovens by the usual style of ram pusher into the common form of hot coke car and quenched in a tower of the usual kind. After discharge on the wharf it was handled by a typical conveyor system through two screening stations. The coke was screened to produce large and small furnace sizes; stove, nut and pea, domestic sizes and breeze. The gas was separated into rich and lean at the battery. Separate test records were kept of each size of coke and of each quality of gas. Practically all of the ammonia produced was made up into sulphate immediately through the direct recovery process. Although the plant operated for the production of pure light-oil products, only the total production of light oil was measured, but the yield of various constituents was determined by analysis.

COAL USED

The coal was apparently clean and very well screened. The impurities consisted of a small amount of pyrite, mostly in the form of thin layers, calcite, mother of coal, and shale. The coal was crushed at the plant with the intention of making it as fine as was feasible with the apparatus available. As charged to the ovens, over 95 per cent passed through a 4-mesh sieve, and about two-thirds passed through a 10-mesh sieve.

A composite sample of the crushed coal sampled from the conveyor belt was made up from the daily plant samples and analyzed according to the laboratory methods described in Bureau of Mines Technical Paper No. 8; the results are presented in Table I.

In Table II is given the total amount of coal used and the average coking time for the period of the test.

PUSHING AMPERAGE

No consecutive record was maintained of the current necessary to push the oven charges. However, sufficient data were obtained to show that, in general, the charges pushed easily, though not as easily as with the usual coal mixture. It generally required from 180 to 250 amp. to start the charge and from 120 to 180 amp

to keep it moving; in an occasional oven the amperage required to start the charge amounted to from 300 to 350, with 200 to 300 amp. required to keep it moving. Very few of the charges stuck, so that it was impossible to push the charge out before the circuit breaker acted; as high as 550 amp. was noted in one or two of these cases. One charge in particular, oven No. 49, on

TABLE I. COAL ANALYSIS AND HEATING VALUE

	As Charged	Dry Basis

Average net	19.11

Sept. 29, gave a great deal of trouble; three attempts were made to push the charge before it was possible to clear the oven. However, in no case was it necessary to rake or dig the coke from the ovens.

HIGH TEMPERATURE MEASUREMENTS

High temperature measurements were made continuously for several days during the test period in order to give an accurate idea of the operating conditions of the battery. Records were taken of the temperature in the oven walls, regenerators, waste-heat flue, in the coal

mass and in the vapor above the coal. Measurement of high temperatures in a by-product coke oven is attended with great difficulty because of the inaccessibility of certain points where temperature measurements are desirable and because of the limited variety and high cost of apparatus which can be used for these purposes. The results obtained are sufficient, however, to give an accurate idea of the range and average temperature maintained at the important points in the heating system.

A complete survey of temperature conditions through the entire battery was, of course, impossible; but rep-

FIG. 3. AVERAGE TEMPERATURE OF HEATING WALL SHOWING EFFECT OF CHARGING AND PUSHING TEMPERATURE RECORDED 7 ft. below top of battery between ovens No. 2 and No. 3

representative points were chosen and the results given in Figs. 3 to 6 inclusive are typical of all operations. During the period of the test certain optical pyrometer measurements were made by the company engineers which confirmed the fact that the locations chosen for our regular measurements were typical.

The general trend of heating wall temperatures, before, during and after charging the adjoining ovens, is given in Fig. 3. These temperatures, of course, are not as high as prevail in certain parts of the wall refractory, for example at the lower regulating brick near the air port, where the maximum temperature is reached. To show the effect of gas and air reversal on the temperature in the heating wall, the curve of Fig. 4 is given.

Temperature measurements were made at three places in four consecutive charges of coal in oven No. 3. Readings were taken with couples 10 ft. long, introduced through charging lids as nearly as possible midway between the oven walls. The mean of the temperature-time curves for these locations is plotted in Fig. 5. Short thermocouples were introduced through the charging lid nearest the pushing end of oven No. 3 to measure the vapor above the coal. Four curves for four consecutive charges are shown in Fig. 6.

Over the checker-brick in the right half of the regenerator under oven No. 3 at the coke and 54 in. in from the face of the regenerator wall the temperature averaged 1140 deg. C. The variation in temperature during reversal of direction of gas burning was about 55 deg. C. at this point. Temperature measurements taken at the junction of the waste heat tunnels from the two batteries averaged 272 deg. C.

COKE HANDLING

During the test, two different systems of screening were used as follows:

Screening System No. 1—The coke was delivered by the conveyor over an inclined-bar-grizzly screen in the first station. The screen was about 5½ ft. long, 4 ft.

wide and consisted of 1½-in. bars spaced from 1¼ to 1½ in. The oversize was delivered in the railroad cars and weighed as "furnace coke." The undersize delivered on a second belt conveyor was carried to a second screening station, where it passed through an inclined-rotary-cylindrical screen, the first half of which consisted of ¾-in. square perforations, and the second half 1½-in. square perforations. The material passing through the ¾-in. perforations was re-screened on a ½-in. shaker screen to separate the breeze and pea size coke. The material passing through the 1½-in. perforations was called nut coke, and that passing over the 1½-in. perforations was classified as stove coke. The breeze, pea, nut and stove sizes were separately loaded in railroad cars and weighed before shipment or storage. Nut and stove sizes, as delivered from their respective bins, passed over shaker feeders before going into the railroad cars. The pea and breeze sizes were thus very completely eliminated from these two domestic sizes.

Since the separation of "furnace coke" by the inclined-bar-grizzly in the first screening station was not considered satisfactory because the screen was not large enough to handle the quantity of coke passing over it and make a good separation, a change was made after three days of the test to the second system, which was as follows:

Screening System No. 2—The inclined-bar-grizzly in the first screening station was discarded and replaced by a 2½-in. rotary grizzly, the oversize of which was delivered directly into railroad cars as "foundry" or "large furnace" coke. The coke passing through the first rotary grizzly was carried to the second screening station, where it passed over a second rotary grizzly set at 1½ in. The oversize of this second grizzly was designated as "small furnace" coke. The material passing

FIG. 4. TYPICAL HEATING WALL TEMPERATURE, SHOWING EFFECT OF REVERSALS

through the second grizzly was separated by the rotary cylindrical screen and sized exactly as in the first system. The furnace coke from the first system and both sizes of furnace coke from the second system, after being weighed, were stacked in a pile at the plant during the test period, so that they were subsequently available for a blast-furnace test as described later. The stove, nut and pea sizes were sold for domestic fuel, as is customary from this plant. The breeze produced was used as boiler fuel at the plant, following the regular practice.

COKE YIELDS

Table III shows the different results obtained from the two screening methods. The results for the entire period are summarized together in Table IV.

It is to be noted that 82.7 per cent of the dry coke produced in screening system No. 1 was classified as furnace coke, oversize of the 1½- to 1½-in. inclined-bar grizzly. As explained under description of screening system No. 1, the separation of the furnace coke by the inclined-bar grizzly was not considered satisfactory, as the screen was not large enough to make a good

TABLE III—RESULTS WITH TWO SCREENING SYSTEMS

Furnace Sizes	Screening System No. 1, Per Cent	Screening System No. 2, Per Cent
Large		18.3

FIG. 5. AVERAGE OF COAL TEMPERATURE CURVES

separation; the very high percentage obtained for furnace size is, therefore, not representative. The total dry furnace coke was only 40.3 per cent of the total dry coke screened during that part of the test when screening system No. 2 was used. However, it should be noted that the yield of stove size is very large, 34.8 per cent of the total coke as screened; there is no doubt that a large amount of the stove size would have been

included in the furnace size if it had been possible to install a 1½-in. inclined-grizzly-bar screen large enough to handle the coke produced and make a good separation.

The small percentage of large-size coke obtained together with the large percentage of the smaller domestic sizes indicated that it would not stand handling and screening without breaking up into smaller pieces, due to the friable and brittle characteristics of the coke.

APPEARANCE OF HOT COKE

The hot coke as pushed from the ovens was observed in order to know the temperature and general performance of each oven and each lot was again observed after

FIG. 6. TEMPERATURE OF VAPOR ABOVE COAL

quenching and dumping on the wharf. By these observations a very complete idea of battery performance was obtained. These observations may be summarized as follows:

The top of the coke mass was, as usual, colder than the rest of the charge. In fact this condition was somewhat exaggerated during the test, as it was impracticable to adjust the battery for the best use of the leaner gas from the Illinois coal when this was to be used for so short a period. From the level of the horizontal flue in the heating wall down to the bottom of the oven the coal was usually thoroughly coked; and in general the heats were uniform for the entire length of the charge. From a number of the charges some uncoked material remained in the center of the charge at the level of the horizontal flue.

From most of the charges a large amount of smoke and flame arose as the coke was pushed from the oven; this was especially noticeable in cases where uncoked material remained at the level of the horizontal flue. The overhang of the coke as it fell from the coke guide into the quenching car was irregular; on the coke side it ranged from 12 to 24 in., while on the pusher side the coke frequently showed signs of crumbling. Immediately ahead of the pusher ram the charge generally crumbled, thus causing a great deal of fine coke. A distinct line of cleavage was noted through the center of the charge in almost all cases.

APPEARANCE OF COKE ON WHARF AND IN CARS

The coke on the wharf was very irregular in size, but on the average the pieces were distinctly smaller than for the average by-product coke mixtures. There was no tendency to blockiness and very few pieces were as large as 6 in. in each dimension. The material was decidedly lighter than the average by-product oven coke, weighing only about 23 lb. per cu. ft. The color varied somewhat, but in general the furnace-size was of a dark silver color.

The coke had a decided longitudinal fracture and many of the pieces before reaching the wharf were broken up into fingers. Even the larger pieces showed a tendency to fingering, and by completion of the decided longitudinal fracture generally these broke up into several smaller pieces before reaching the cars. There was no apparent cross-fracture, but the brittleness of the long fingers was such that these frequently broke up into two shorter pieces during handling.

In the railroad cars the furnace size from screening system No. 1, in which a $1\frac{1}{2}$ -in. inclined-bar-grizzly screen was used, consisted mainly of small fingers from 1 by $2\frac{1}{2}$ in. up to a maximum of about 2 by 6 in. There were very few blocky pieces about $2\frac{1}{2}$ by $3\frac{1}{2}$ in. The oversize of the $2\frac{1}{2}$ -in. rotary grizzly, used in screening system No. 2, in the cars was about half fingery and half blocky coke, averaging much larger than from screening system No. 1. The small-furnace size from this second system, through the $2\frac{1}{2}$ -in. but over the $1\frac{1}{2}$ -in. rotary grizzly, averaged about 2 by $2\frac{1}{2}$ in. The great difference in size between the coke on the wharf and after loading in the cars shows the decided tendency to breakage during handling.

The cells of the coke were small and regular and in general of a structure indicating suitable characteristics for furnace use. There was no sponge formed, but there was a decided tendency to form a pebbly seam at a distance of 2 to 6 in. from and, in general, parallel to the oven wall. This seam appeared only in a part of the pieces in which it formed an incipient cross-fracture. In general there were no pebbly seams in the coke at the bottom of the oven. The small amount of pebbly mass noted seemed to come from the top and center of the oven in the form of small loosely-cemented lumps of material which were readily crumbled in the hands. Although the coal contained considerable "mother of coal," there was very little evidence of "foreign matter" in the coke, probably because of the fineness to which the coal was crushed.

COKE ANALYSES AND TESTS

Each size of coke was carefully sampled for analysis and for determination of moisture content in order to correct to true weight at the time it was loaded in the railroad cars.

The results of proximate and ultimate analysis and heating value determination of the composite sample of each size of coke are given in Table V.

TABLE V—COKE ANALYSIS AND HEATING VALUE

	Furnace Coke—		Domestic Coke—		Coke Breeze—	
	As Loaded	Dry	As Loaded	Dry	As Loaded	Dry

The weight per cu.ft. of furnace coke was determined on one car of large furnace coke and also on one car of small furnace coke. This was done by leveling the cars and making the calculations from the net weights of coke and the rated cu.ft. capacity of the cars.

Apparent specific gravity determinations were made on three composite samples of furnace-size coke and an average of these is given as representing the entire lot. A single composite was made up for the entire lot and the true specific gravity determined. The porosity of the coke was calculated from these results for apparent and true specific gravity. These physical properties of the furnace coke may be summarized as in Table VI.

TABLE VI—CHARACTERISTICS OF FURNACE COKE

Weight per Cubic Foot of Dry Coke:	
Furnace size from screening system No. 1.....	23.4 lb.
Large furnace size from screening system No. 2.....	22.8 lb.
Apparent specific gravity.....	0.88
True specific gravity.....	1.85
Porosity.....	52.4%

BLAST-FURNACE TEST

In order to test the behavior of the furnace-size coke produced from the Orient coal, arrangements were made to use about 1800 tons of this material in the blast-furnace plant of the Mississippi Valley Iron Co. The coke regularly used at that furnace is produced in Koppers ovens of the Laclede Gas Light Co., St. Louis, from a mixture of Elkhorn, Pocahontas (low volatile) and Illinois coals. The substitution of the Illinois coke for the regular supply was accomplished abruptly and continued without interruption throughout the ten-day period. Several experts were present during this test, and it was the unanimous opinion of these persons and of the blast-furnace operators that the Illinois coke had shown highly satisfactory results. However, it should be borne in mind that the furnace used for this test was of small capacity, and it is not certain, therefore, that the results in this case would be duplicated on a large-size furnace.

SPECIAL OVEN TESTS

In order to study the effect of lower temperature and longer time of coking, and to get some idea of the value of certain special coal mixtures, a few ovens were operated under different conditions than normal. The lower temperature trials were made in oven No. 1 during the period of the test by cutting down the quantity of gas burned in the heating walls of this oven. The special mixtures were made up at the end of the test period and tried out in one or more ovens.

Low Temperature Coking of Orient Coal.—Oven No. 1 was changed from its regular operating period beginning Oct. 1 and three charges of distinctly longer periods, 22 $\frac{1}{2}$, 23 $\frac{1}{2}$ and 25 $\frac{1}{2}$ hr., were pushed on Oct. 3, 4 and 5 respectively. The temperature of this oven was from 50 to 100 deg. C. lower than the temperature of the remaining ovens in the battery. The coke from these special tests was very similar to that obtained from the same coal coked for the usual 19-hr. period in that the cell structure was not materially different and that there was the usual small amount of "foreign matter" and no sponge. However, the material as it lay on the wharf appeared decidedly larger and blockier and there was slightly less of the pebbly mass or pebbly seam. The blocks of coke were decidedly stronger, judged both by their action when handled and by the shatter test described below. The results of this special work at lower temperatures were very closely comparable with the results obtained at Dover, Ohio, when using the same coal in a narrower oven and coking at a corresponding rate, measured in inches of coke formed

per hour. It is evident from these tests that stronger, larger coke will be obtained at the somewhat lower temperatures used in this work than at the temperature at which it was necessary to operate during the full test at St. Paul in order that the gas supply of the city would not be interrupted.

Mixture of Orient and Pittsburgh Coals.—In order to study the character of coke produced from a mixture of equal parts of Pittsburgh and Orient coals, a single oven was charged with this mixture. Oven No. 60 was charged 5:30 p.m. Oct. 7 and pushed 11:30 a.m. Oct. 8; the charge was 25,100 lb. The coke from this 18-hr. test was thoroughly coked, but the appearance on the wharf was not encouraging. There was decided longitudinal fracture, indicating the fingery tendency common to high volatile coals, but the coke was fairly tough. The cell structure resembled that of Orient coal alone, except in the upper central section of the oven, where considerable sponge was formed. There was no noticeable cross-fracture, but the irregular shapes showed that the breakage of the material in regular handling would probably be rather high. The pebbly seam so frequently noted in coke from 100 per cent Orient coal was not apparent in this single test; but the tendency of Pittsburgh coal to produce sponge was not counteracted by the mixture.

Mixture of Orient and Pocahontas Coals.—A mixture of 25 per cent Pocahontas and 75 per cent Orient coal was used in three ovens charged on Oct. 7 and pushed after approximately 17 hr. of coking. In each case the charge was about 25,200 lb. The coke produced under these conditions was blocky and on the average of large size, but the pieces were very irregular. There was no tendency to finger, but a decided cross-fracture was shown. The coke, although appearing soft, was unusually tough, as will be evident from the high percentage unbroken in the shatter test. The cell structure was irregular and the general appearance of the material on the wharf would have indicated under-coking, but the appearance while hot, as it was pushed from the oven, showed that this was not the fact. The very small percentage of fine material indicated that an unusually high percentage of furnace-size would be available from this mixture.

Shatter Test of Special Cokes.—In order to get a rough check on the relative strength of the different special cokes which were made, a shatter test was carried out on each of the samples. For this test a 50-lb. sample of large pieces of coke taken from the belt, none of which pieces would begin to pass through a 2-in. square mesh screen, was dropped four times from a height of 6 ft. onto an iron plate. The pieces of coke which following this test would not in any position pass through the 2-in. screen were weighed and their ratio to the weight of the original sample was taken as the "percentage unbroken" in results indicated below.

The usual foundry mixture, consisting of 30 per cent Pocahontas, 35 per cent Pittsburgh and 35 per cent Elkhorn coal, was found to give a result of 68 per cent unbroken by this test. The straight Orient coal coked for 19 hr. gave a coke of which only about 27 per cent remained unbroken by this test. The coke obtained from 22- to 26-hr. coking periods was somewhat stronger, ranging from 27 to 33 per cent unbroken. The mixture of 50 per cent Orient and 50 per cent Pittsburgh showed about 53 per cent unbroken, and the

mixture of 25 per cent Pocahontas with 75 per cent Orient was strongest of all, with 74 per cent unbroken.

The above results are merely an indication and must not be taken as any accurate measure of the strength, since only a limited number of tests were made. Large irregularities are always found in this kind of testing and moreover this test is not strictly significant as to the strength of the material, since at the best it really gives an accurate measure only of the likelihood of breakage during handling.

BY-PRODUCTS AND GAS PRODUCED

The results obtained during six days from 8 a.m., Sept. 29, 1918, to the same hour Oct. 5, 1918, were used as the basis for by-product and gas results, since during this period only Orient coal was in use and the system contained only products from this coal. During this period 6092.3 tons of natural coal were charged to the ovens, equivalent to 5600.6 tons on the dry basis, and these figures are used in calculating the yield of tar, ammonium sulphate, light oil and its products, and gas, which are reported in the following sections.

TAR AND AMMONIA

During the test, daily inventory was taken of the quantity of the tar and liquor in stock, accurate weights and specific gravities of tar shipments were recorded, and other necessary arrangements made to permit accurate determination of the quantities of these materials produced.

It was the intention during the test to produce only ammonium sulphate and maintain the minimum practicable supply of ammonia liquor. However, a slight variation in the quantity of liquor at the beginning and end of the test inevitably resulted, and appropriate correction for this difference in inventory was made and appears in the record of results reported. Samples of the tar, liquor and sulphate were taken for analysis regularly, so that the quality as well as the quantity of these materials would be a matter of record.

TABLE VII—YIELD AND CHARACTERISTICS OF TAR

Tar produced, as measured, gal	47,560
Tar produced, dry (computed), gal	46,100
Tar, as produced, per ton of coal as charged, gal	7.81
Tar, dry, per ton of dry coal, gal	8.23
Water in tar, by weight, per cent	2.6
Specific gravity, as produced	1.187
Specific gravity, dry basis (computed)	1.192

TABLE VIII—YIELD OF AMMONIUM SULPHATE

Produced, scale weight, lb	155,510
Produced, pure, lb	151,100
Equivalent in liquor, start of test, pure, lb	15,920
Equivalent in liquor, end of test, pure, lb	34,700
Equivalent due to liquor increase, pure, lb	18,780
Total production, pure, lb	169,850
(NH ₄) ₂ SO ₄ per ton of coal as charged, lb	27.68
(NH ₄) ₂ SO ₄ per ton of dry coal, lb	30.33
NH ₃ per ton of coal as charged, lb	7.19
NH ₃ per ton of dry coal, lb	7.82
Average of NH ₃ in ammonium sulphate produced, per cent	25.06

The sulphate delivered from the saturators into wheelbarrows was weighed as it was conveyed from the saturator room to the storage pile. The weight of sulphate produced daily varied largely in accordance with the amount of ammonia liquor accumulated or worked up into the sulphate during the day. From the measurement of volume, the temperature, specific gravity, and per cent of NH₃ by weight, as determined in the laboratory test, the pounds of NH₃ and the equivalent weight of (NH₄)₂SO₄ were computed for the initial and final inventories.

LIGHT OIL

The rich and lean gas produced at this plant are separately scrubbed for light oil recovery, but the light oil separated from the wash oil in the stripping stills is collected together. During the test period two sections of the light oil "running tank" were used on alternate days in order to permit careful measurement of each day's light oil production.

Table IX gives the total production of light oil for the six-day by-product period and the yield based on the analysis of the composite sample analyzed according to methods prescribed in Ordinance Publication No. 1800.

TABLE IX—LIGHT OIL YIELD AND ANALYSIS

Produced, gal.	22,570
Composition:	Per Cent.
Boiling under 200 Deg. C. (Engler Flask)	84.4

Heat in Gas per Pound of Dry Coal:	B.t.u.
In surplus gas	1,690
In gas to ovens	1,390
Total	3,080
Heat in Gas Used to Coke Coal, Per Cent	45.2

GAS

The gas produced at the plant was separated at the ovens into rich and lean, the quantity of rich gas being so regulated as just to supply the requirements for

the St. Paul Gas Light Co., to which all of this gas is sold. The lean gas remaining was used for heating the battery, and, if there was any excess, for firing the boilers.

The average analysis and total production of gas for the six-day by-product test period, together with the yield per ton of coal and relative heating value calculations, are presented in Tables X and XI.

SUMMARY

As a result of the test it is clearly demonstrated that some of the Illinois coals can be coked in the "chamber-type" oven without radical change in operating methods for the production of coke which can be successfully used in a blast-furnace. However, it appears that the temperature at which Illinois coal should be handled for the production of the best coke is somewhat lower than the best operating temperatures for Eastern coals and moreover the speed of coking of the Illinois coal is somewhat less. The yield of gas and by-products from Illinois coal of the kind tested is excellent both in quantity and quality. Of course the coal tested in this case represents one of the best Illinois coals for coking purposes, being lower in ash and sulphur and otherwise superior to many from this field.

In general, the comparison of Eastern coking coals with those from the Mid-Continent field must be made upon an economic basis, since which source will be preferable depends altogether on local conditions which will affect the cost of the material and the relative expense of handling. These phases of the question have, however, not been discussed in this report.

ACKNOWLEDGEMENTS

The authors wish to acknowledge the assistance and co-operation of the engineers and chemists who were associated with them in this work, as well as that of Mr. T. G. Janney, manager, and Mr. K. G. Richards, superintendent, of the plant, and Mr. F. W. Sperr, Jr., chief chemist of the Koppers Co., all of whom did all in their power to make the work both pleasant and successful. Special acknowledgement is also made of the great assistance which Mr. I. V. Brumbaugh has given us in working up the data contained herein and in preparing this manuscript.

Washington, D. C.

A. I. M. E. to Have Large Program at Chicago Meeting

From a technical point of view, the Chicago meeting of the Institute, Sept. 22 to 26, promises to be one of the most interesting in its history. The wealth of material in the line of technical papers for discussion is greater than has been offered for any previous meeting; upward of 150 papers have been submitted to the committee, who find it no small task to arrange a program to present this number with a minimum of conflicts among papers on allied subjects.

One of the excursions to be made by the Institute as a body during this meeting is to the LaSalle district. A special train in leaving Chicago early Thursday morning will take the members and guests to LaSalle, Ill., where automobiles will convey the different parties to the coal mines, cement works and zinc smelters. For the ladies, and others of the party not particularly interested in these industrial operations, the LaSalle hosts plan an automobile trip to Starved Rock.

The Economic Status of American Chemical Industry

BY FREDERICK E. BREITHUT

Major, Chemical Warfare Service, U. S. Army

THE accompanying charts are based on the statistics given in the Census of Manufactures for 1914. They try to give some idea of the relation of chemical industry to the total of industry of the country.

In endeavoring to present a picture of chemical industry as a whole one is immediately confronted with the difficulties of classification. The Census of Manufactures for 1914, for example, considers the group "chemical and allied products" as including "not only the industries whose products are chemicals in the ordinary sense of that term, but also the industries which employ to a large extent chemical processes in manufacture." In the introduction to the consideration of this group it is remarked: "The group is a very compli-

cated one and the various products differ most widely in the character and in the use to which they are put. There is considerable duplication in the combined value of products for the group, due to the use of the products of certain industries as materials for others."

The Census of Manufactures for 1914 divides all manufactures into fourteen general groups as follows: (1) Food and kindred products, (2) textiles, (3) iron, steel and their products, (4) lumber and its remanufacture, (5) leather and its finished products, (6) paper and printing, (7) liquor and beverages, (8) chemicals and allied products, (9) stone, clay and glass, (10) metal and metal products other than iron and steel, (11) tobacco manufactures, (12) vehicles for land transportation, (13) railroad repair shops, (14) miscellaneous industries.

The group "chemicals and allied products" is subdivided in turn into twenty-four sub-groups, as follows: (1) baking powders and yeast, (2) blacking stains and dressings, (3) bluing, (4) bone, carbon and lampblack, (5) candles, (6) chemicals and acids, (7) cleansing and polishing preparations, (8) coke, not including gas-

Abstract of the Census of Manufactures, 1911. CHEMICAL & METALLURGICAL ENGINEERING, Vol. 19, 68, pp. 371-386.

house coke, (9) drugs, etc., (10) dyestuffs and extracts, (11) explosives, (12) fertilizers, (13) gas, illuminating and heating, (14) glue, not elsewhere specified, (15) greases, (16) ink, printing, (17) ink, writing, (18) oils, (19) paint and varnish, (20) petroleum, refining, (21) salt, (22) soap, (23) turpentine and rosin, (24) wood distillation, not including turpentine and rosin.

Of these sub-groups, the item "chemicals and acids" is again subdivided into twelve parts, as follows: (1) acids, (2) sodas and sodium compounds, (3) potash and potassium salts, (4) alums, (5) coal-tar products, (6) cyanides, (7) bleaching materials, (8) chemical substances produced by the aid of electricity (including those belonging under other groups), (9) plastics, (10) compressed or liquefied gases, (11) fine chemicals, (12) chemicals not otherwise specified (such as glycerine, cream of tartar, epsom salts, blue vitriol, copperas, etc.).

On the other hand, the monograph entitled "chemicals and allied industries" of the series issued on the

basis of the Census of Manufactures for 1914 includes the twelve subdivisions just enumerated, and in addition fertilizers, paints and varnishes, explosives, dyestuffs and extracts, wood distillation, essential oils, bone, carbon and lampblack. To the busy man seeking information on chemical industry as a whole, or the relationship of a particular part of the industry to the whole chemical industry or to the industry in general, the picture is one of confusion. Under the circumstances it is only natural to find that dissatisfaction has been expressed concerning the present state of our chemical statistics. Thus Bernhard C. Hesse,² in 1915, presented a plan for a revision of our chemical statistics which resulted in the appointment of a committee of the American Chemical Society "to devise some practical and practicable way of obtaining such revision and of putting it into useful and serviceable effect." As chairman of this special committee of the American Chemical Society, Dr. Hesse³ prepared a consolidated list of articles used or produced in or by chemical industries as they appear in the most diversified commercial reports.

Accepting for purposes of comparison the data given in the 1914 Census under the heading "Chemicals and Allied Products" as related to industry as a whole, the charts shown herewith may be regarded as giving a general survey of the economic status of American chemical industry just prior to the outbreak of the world war.

Chart I shows that of the 275,791 manufacturing establishments in the United States in 1914, 12,374 were engaged in chemical manufacture. This constitutes 4.49 per cent of the total establishments and places the group "Chemicals and Allied Products" in the ninth place in the order of number.

Chart II arranges the fourteen groups in the order of their importance from the standpoint of the value of their products. In this respect "Chemicals and Allied Products" ranks fourth, with a value of \$2,001,634,000, constituting 8.3 per cent of the total.

Chart III shows the groups from the standpoint of

²Jour. Ind. & Eng. Chem. 7, 58.

³Jour. Ind. & Eng. Chem. 8, 749; METALLURGICAL & CHEMICAL ENGINEERING, Vol. XV, No. 5.

cost of materials entering into the industry, and in this respect "Chemicals and Allied Products" ranks fourth, with a value of \$1,289,348,000, constituting 9.0 per cent of the total.

Chart IV arranges the groups in the order of their importance from the standpoint of capital invested. In this regard "Chemicals and Allied Products" ranks second, with a total capital investment of \$3,034,209,000, constituting 13.31 per cent of the total.

Chart V arranges the groups in the order of their importance from the standpoint of the number of wage earners. In this regard "Chemicals and Allied Products" ranks tenth, employing 299,569 workers, which constitutes 4.3 per cent of the total.

Chart VI arranges the groups in the order of their magnitude from the standpoint of the value added by manufacture. In this regard "Chemicals and Allied Products" ranks seventh, the value added by manufacture totaling \$712,286,000, constituting 7.2 per cent of the total.

Chart VII shows the per cent of value added by manufacture for each of the fourteen groups. In this regard "Chemicals and Allied Products" ranks eleventh, with 35.6 per cent. (The average per cent of value added by manufacture for all industries is 40.7 per cent.)

Having shown the picture of the status quo of industry as a whole and of its large groups as it existed in 1914, an attempt was made to get an idea of the growth of these industries for the period 1904-1914. The results are shown in Charts VIII, IX and X.

Chart VIII shows the per cent of increase in value of products in the period 1904-1914. In this regard "Chemicals and Allied Products" ranks second, being exceeded only by "Vehicles," which includes automobiles. The per cent of increase in value of products is 86.1, which is much above the average for all industry (63.9 per cent).

Chart IX shows the per cent of increase of value added by manufacture in the period 1904-1914. "Chemicals and Allied Products" ranks fifth. The per cent of increase for chemicals, etc., in this respect is 61.3, which is a little above the average for all industry (57.0 per cent).

Chart X shows the per cent of increase in number of wage earners in the period 1904-1914. In this respect

comment. An attempt to gage how great this growth has really been may be interesting. To this end the usual sources of information were consulted—trade journals, the files of the governmental bureaus in Washington, the manufacturers themselves. Table I shows the 1914 and 1917 figures for the more important chemicals.

The Explosion of Chemicals—II* Workmen's Compensation Acts

BY CHESLA C. SHERLOCK

IN our discussion of the liability of an employer to injured employees under the common law, we found that certain abuses had crept into the common law practice which made it practically impossible for an injured workman to recover damages for his injury. His right of recovery was limited to a very small percentage of the cases arising, and then his recovery depended upon his ability and resources sufficient to overcome his employer in a legal battle before the courts. The common law liability was founded entirely upon the theory of fault. Let the fault for the act be determined, and then the party at fault had the damages assessed against him. Only in a limited sense was this fault ever found to lodge entirely against the employer.

The narrowness of the common law soon gave rise to a spirit of unrest among the laboring classes and also among certain employers who had been forced to pay damages to injured workmen. These employers found that when a workman did recover he generally recovered an excessive damage, because the amount he was entitled to was left entirely to the whims of the jury. So the demand came for a new system of liability which would eliminate legal controversy, definitely fix the employer's liability so that he could anticipate it and guard against financial loss by means of insurance, and at the time guarantee the payment of such damages to injured workman at the time when the damages were most needed.

The theory of the compensation acts is not based upon fault at all, but it is based upon the idea that all injuries suffered by accident in the course of the employment should be compensated. It is said that during his productive years the workman contributes to the wealth of society. Then, when industry contributes to rob him of his earning power by incapacitating him, society or industry should share the loss with him.

COMPENSATION NOT DAMAGES

Compensation is not in any sense damages. The compensation acts do not attempt to indemnify the workman for the actual loss sustained, but to merely share that loss with him. So we find that the compensation acts usually determine the amount of the loss sustained by the workman by ascertaining his average wages for the year next preceding the date of injury and then dividing that by one-half or two-thirds or whatever percentage the statute has determined the industry should bear and making that proportion the amount the employer shall pay.

The compensation acts go farther and absolutely deprive his employer of his common law defenses, so that it is practically impossible for the employer to delay

TABLE I. APPROXIMATE VOLUME OF BUSINESS IN 1914
AS COMPARED WITH 1917

Class	1914	1917
1. Coal tar erudies, intermediates, dyes,	\$25,000,000	\$70,000,000
2. Drugs and pharmaceuticals	68,000,000	150,000,000
3. Essential oils, flavoring and perfumery materials	10,000,000	10,000,000
4. Explosives	41,000,000	500,000,000
5. Fertilizers	203,000,000	258,000,000
6. Heavy chemicals	39,000,000	177,000,000
7. Mineral acids	26,000,000	100,000,000
8. Miscellaneous inorganic chemicals	55,000,000	100,000,000
9. Miscellaneous organic chemicals	115,000,000	215,000,000
10. Natural dyestuffs and tanning materials	30,000,000	56,000,000
11. Paints and varnishes	149,000,000	175,000,000
12. Proprietary preparations	105,000,000	200,000,000
13. Soaps and glycerine	136,000,000	232,000,000
14. Wood distillation products and naval stores	35,000,000	76,000,000

"Chemicals" ranks sixth, with an increase of 31.8 per cent, whereas the average increase was 28.0 per cent.

The remarkable growth of American chemical industry under the stress of war has been the subject of much

*The statistics of capital have been frequently referred to in the reports of previous censuses as defective, and in fact almost worthless, and it has been repeatedly recommended by the census authorities that the inquiry should be omitted from the schedule. Experience at the census of 1914 confirms the belief that the statistics are of little value.—*Abstract of the Census of Manufactures, 1914, p. 11.*

*The first article on this subject, on "Common Law Liability," appeared in CHEM & MET. ENG., July 15, 1919, Vol. 21, No. 2, p. 53.

or evade payment. They likewise deprive the employee of his common law rights, so that he can recover compensation and nothing more. Injuries that are reasonably common are set out in the act and the workman is allowed a specific number of weeks' compensation, so that he knows and the employer knows at once just the exact amount that is due. In other cases, particularly of temporary disability, the employer is to pay so long as the disability continues.

This is fair and just to both parties concerned. The employer in no case is called upon to pay an excessive judgment, as was formerly the case, and the payments are distributed over a number of weeks so that their payment will not financially embarrass him or throw him into bankruptcy. On the other hand, the workman is sure of getting his award and without the necessity of legal expense or a long protracted fight in the courts. The basis of recovery under the compensation acts is limited to those injuries causing incapacity through an accident arising out of and in the course of the employment.

It is not the purpose here to give an extended exposition of the decisions upon the compensation acts, as such would be impossible in the short space possible for this review of the matter. The question of what is an accident is pretty well settled at this time. The courts are practically united in saying that an accident is an unlooked for and untoward event happening within chance and without design or intention. They have said that under the compensation acts the term shall be given its ordinary and usual meaning and shall not be construed as employed in a technical sense.

ACCIDENTS MUST BE IN COURSE OF EMPLOYMENT

There is no doubt that an explosion of chemicals in the ordinary sense would clearly be termed as an accident under the compensation acts. But this is not sufficient to establish the employer's liability. The accident must arise "out of and in the course of the employment." If the workman is regularly engaged in the duties of his employment and is proceeding in a usual and careful manner and an explosion occurs which clearly arises out of the employment of that particular workman, then he would be entitled to compensation.

But if the workman is outside the course of his own employment, even though the accident arose out of the general employment, he is not entitled to compensation. That is to say, if a workman is employed at his own task, but goes over to the bench of a fellow workman and meddles in his work so that an explosion takes place, he is not ordinarily entitled to compensation, because he is outside the course of his employment.

There are numerous decisions upon this point, but I think one will serve to illustrate the trend of the courts. A workman while on his way to a toilet paused at the bench of a fellow workman and commenced to play with some dynamite caps which the other workman used in his work. As a result there was an explosion causing the loss of several fingers and other severe injuries. He was not given compensation because he was outside the course of his employment at the time accident arose.

There are certain other limitations placed upon the employer's liability which it is well to keep in mind.

"HORSE PLAY" BARS COMPENSATION

If the workman is injured as the result of "horse play" or practical jokes on the part of other workmen he is not entitled to compensation, as it has been held again

and again that horse play is not within the course of the employment. This is an unfortunate situation because the victim of the prank is nearly always innocent of any wrong doing, yet is made to suffer the burden of his fellow workmen's pranks.

While there is no legal liability imposed upon the employer in such cases, there is certainly a moral obligation imposed upon him to stop such practices as soon as he discovers them among his employees. If the employer goes to the trouble to tell his men just what happens in cases of injury and tell them of specific cases where harmless pranks have resulted in grave disaster, it will generally be sufficient to remove any chance of injury to innocent workmen.

If a workman is guilty of "serious and willful misconduct" and such misconduct is the cause of his injury, he cannot recover compensation. This generally refers to the manner in which he obeys his employer's instructions or the manner in which he does the work he is required to do. It would certainly be willful misconduct for a workman to willfully explode a charge of chemicals, even though he did it in a spirit of fun or experimentation. Unless such an act was clearly within the scope of his employment, he would not be entitled to recover compensation from his employer.

ANOTHER'S MALICIOUS INTENTION BARS PAYMENT.

The employer is not liable for the payment of compensation in cases where the workman is injured by the malicious intention of another. If two workmen get into a fight and one is injured through the malice of the other, no liability attaches to the employer. Furthermore, the employer is not liable under the compensation acts for the payment of compensation to casual workers, or those employed at casual work, such as window washers and those who are employed only for odd jobs at irregular intervals.

The employer generally is not liable for the payment of compensation to those who are not engaged in hazardous employment. He is not ordinarily liable to clerks and office help, or any one who falls within the clerical class, unless in the course of their work they are subjected to the hazards of the business.

The only way that the employer can determine his specific obligation under the compensation act is to refer himself to the statute under which he is operating. They vary in details in the respective jurisdictions. However, the main points given above are practically general rules in force wherever the compensation practice is followed, and they are supported by the great weight of judicial authority.

The compensation acts intend to exercise fairness and honesty among all classes and when they are administered in the true spirit they are a distinct improvement over the old common law system.

Glass and Glass Sand

In spite of the approach of national prohibition the demand for certain lines of glassware normally used in the dispensing of beverages to be banned has continued. In addition a new demand has arisen in unexpected volume for glassware to be used in the serving of soft drinks. This class of trade is now demanding an even better quality than was commonly sold for bar service. It is expected that soft drinks and near-beers will greatly increase in popularity and this new trade should eventually largely replace that lost in beer and liquor bottles.

The Nelson Electrolytic Chlorine Cell*

Development and Description of the Cell—Technology and Special Features: Simplicity of Structure, Graphite Anode, Durability, Floor Space, Attendance, Quality of Chlorine and Caustic and Electrical Efficiency

By C. F. CARRIER, JR.†

SUCH a number and variety of electrolytic chlorine cells have been described in the patent and technical literature, or presented before the scientific societies from time to time, that it is with some diffidence we ask attention to this somewhat threadbare topic. Only some extraordinary feature would entitle a chlorine cell to a place on the program of the American Electrochemical Society.

Most chlorine cells have been introduced to the scientific world in their early patent or experimental stages, and many remarkable devices have been described and efficiencies claimed which for some reason have seldom materialized in practice. The Nelson cell is not a novelty of the hour, nor does it yield any theoretical results which have not been previously claimed for other cells, but surely the most extensively used chlorine cell in the world must possess some features of practical importance that are worthy of careful analysis, and we therefore give publicly for the first time a complete history, description and record of its commercial application. It has been the author's privilege to erect and operate three large plants using this cell, therefore the subject can be treated with intimate practical knowledge as well as with the co-operation of the inventor.

DEVELOPMENT OF CELL

This cell was developed by Mr. Harry R. Nelson of the Warner Chemical Co., at Carteret, N. J. It was the desire of this company to secure a supply of comparatively pure chlorine gas for use in the manufacture of chlorine chemicals other than bleach. With this aim in view, they began the production of chlorine about 1905 and it might be mentioned in passing that one of the oldest chlorine plants in the United States has been successfully operating for fourteen years on New York harbor with power that was not hydraulically generated.

The first installation consisted of McDonald cells. These are essentially three-compartment cells. Two perforated metal cathode plates support the asbestos diaphragm and divide the cell into a middle anode compartment and two outer, or cathode, compartments. Graphite anode blocks with lead lugs were suspended from an earthenware cover box and the diaphragm was held in place by masses of cement concrete in the bottom and ends of the anode compartment. The cathode compartments were filled with caustic soda solution to about the same level as the brine in the anode compartment. Besides a very low ampere efficiency, this cell gave many operating troubles and the upkeep was excessive.

In 1908 it was determined to investigate the relative merits of mercury cathode and diaphragm cells. Mr.

Nelson worked on the improvement of the diaphragm cell and the author developed a mercury cathode cell. As a result of these tests, it was decided by all concerned that the diaphragm type of cell was better adapted to the needs of the Warner Chemical Co. and further effort was directed to the improvement of the diaphragm cell. The McDonald cells were so materially altered that they completely lost their identity and a new cell was built which was the progenitor of the Nelson cell.

Much of the trouble with the McDonald cell was attributed to the use of concrete in the anode compartment. This was eliminated in the Nelson cell of 1908 by making the perforated metal cathode plate U-shaped and closing the ends of the anode compartment thus formed, by means of slate slabs. This was a great improvement, but the caustic compartment was still filled with caustic liquor and the ampere efficiency was still lower than was desired.

It was soon found that better results were obtained by leaving the caustic compartment empty and allowing the caustic and brine solution to drip from the diaphragm, but there was still some trouble due to decreasing percolation and increasing resistance as the operating period lengthened.

In 1913, these difficulties were overcome by the introduction of steam into the cathode chamber and the cell assumed the final form to be described below. This unique improvement was followed by the discovery of a process for treating the graphite anodes which more than doubled the life of the graphite, and later by the development of an automatic feeding device, details which will be discussed further below under "description" and "special features."

The culminating development has been during the period of the war, there now being in operation over

FIG. 1 INSTALLATION OF CHLORINE PLANT

*Extract of a paper read before the American Electrochemical Society, New York, April 3-5, 1919.

†American Cyanamid Co.

‡U. S. Pat. 697,157, April 8, 1902.

twenty plants in various parts of the world. Nearly 8000 cells have been installed, rated at 1000 amperes capacity and representing a daily output of about 200 tons of chlorine gas. The largest single chlorine plant in the world is the United States Government plant at Edgewood Arsenal, Baltimore, Md., where over 3500 Nelson cells were installed for the production of 100 tons of chlorine gas per 24 hours. The construction of this plant was one of America's greatest chemical achievements during the war. It was built at a moderate cost, only 7 per cent above the estimates, which had not included overtime; it was ready to operate on the date promised and was completed without alteration of the plans after construction had been started. The other large chlorine plants of the world have been built in sections from time to time over periods of many months, while the Edgewood plant, the largest of them all, was entirely built in four months.²

DESCRIPTION OF THE CELL

A description of the cell is to be found in U. S. P. 1,149,210 of Aug. 10, 1915, but a much better idea of the general construction can be obtained from the accompanying illustration. Special attention is called to the simplicity of the design. A substantial, rectangular tank made of $\frac{1}{2}$ -in. steel plate forms the body of the cell. In this is mounted a U-shaped cathode plate of perforated sheet steel, which also acts as the form for the anode compartment. The asbestos diaphragm is supported by the cathode plate and the ends of the U-shaped anode compartment are closed by blocks of cement mortar. An inverted, rectangular box formed of slate slabs closes the top of the anode compartment and also acts as a support for the graphite blocks which form the anode. The anode structure is so clearly shown in the illustration that it only remains to be said that the blocks are 4 x 4 x 17 in. and the lugs are $2\frac{1}{2}$ in. diameter by 12 in. long. It is to be noted that there is but one joint in the graphite, thus insuring maximum conductivity. The positive terminal is connected by means of a flat copper bar bolted to the lugs of the anode blocks, while a copper plate riveted to the perforated cathode performs a similar service for the negative terminal.

The latest built cells, like the illustration, are operated with an automatic feeding device which is very simple and which has proved to be entirely reliable. It consists of a strongly buoyant float on which is mounted a dull knife edge which presses against a bit of rubber tubing through which the brine is supplied to the cell. The slightest rise of the float cuts off the feed entirely and the least drop permits the flow to start again. No trouble is caused by dirt in the brine, because all of the brine is purified before passing to the cells, it being quite essential in the operation of any electrolytic cell for chlorine manufacture that iron, alumina, lime and magnesia be substantially absent.

The brine percolates through the diaphragm and the rate of flow is kept uniform by means of an atmosphere of steam that is maintained in the cathode compartment. This steam also helps dissolve the caustic soda formed at the cathode as well as heating the cell and thus reducing the resistance of the cell. In case the pores of the diaphragm begin to close, as will be shown by excessively strong caustic liquor, they can be freed by increasing the amount of steam.

FIG. 2. NELSON CELL

The normal operating period between renewals of the diaphragm is from six to eight months and during this time the operating conditions remain practically constant. The cells are rated at 1000 amp., at which point the most efficient results are obtained, but they can be run as low as 600 amp. without serious loss of efficiency and will stand a continuous overload of 10 per cent without damage to plant or product. The voltage drop, averaging the switchboard reading and including all connections and cables, for a series of sixty cells, is from 3.5 to 3.8 volts and will usually average 3.7 volts over a period of six months. Only careless operation will cause an increase of more than 0.2 volt in the course of a six months' operating period.

The commercial guarantee under which these cells are sold specifies that, when operated at 1000 amp. and supplied with not to exceed 120 lb. of salt, each cell will produce 60 lb. of chlorine and 68 lb. of sodium hydroxide per 24 hours. For the first few days the caustic liquor flows very freely and is abnormally high in salt, but when the cells have reached normal working conditions the liquor will contain 10 to 12 per cent NaOH and 16 to 14 per cent NaCl.

TECHNOLOGY AND SPECIAL FEATURES

The normal operating period is six to eight months. At the end of this period it is considered better to renew the diaphragms and wash out the cells even if the operating conditions still seem very good, for they may become worse very rapidly if the period is stretched too far. The ordinary anodes are simply impregnated to prevent the electrolyte from creeping to the copper contacts, and only part of these will last more than two operating periods, that is, 12 to 15 months. A new process of treating the graphite has been perfected which increases the life of the anode to more than two years.

One of the greatest features of this cell is that it can be shut down either accidentally or intentionally for short or for long periods as often as desired without damage to the cell or serious loss of efficiency. To the best of our knowledge this is the only commercial chlorine cell that can stand frequent shut-downs without serious consequences.

Simplicity of Structure: Few, simple parts usually mean quick installation and low repair costs. The former was well illustrated at the Edgewood Arsenal plant and the latter has been borne out by the cost records of several large plants over long periods of operation. It also keeps down installation costs and operating expense, as it is possible to operate with ordi-

²See CHEM. & MET. ENG., Vol. 21, No. 1, July 1, 1919, p. 17.

nary labor. There are no moving parts and the entire structure is rugged and durable.

The Anode: The anode is made up of the most economical shape and size of graphite obtainable. Any change in the relative dimensions results in a higher price per lb. The machine work is extremely simple, permitting rapid production with minimum labor. The original appearance of the anode blocks can be seen in the illustration of the cell and in the center of the two illustrations showing anode blocks only. Illustration No. 3 shows a set of anode blocks with no special treatment which have been run 12 months without renewal of the diaphragm. Illustration No. 4 shows a set of specially treated anodes which have been in service six months before the diaphragm was changed and then for a year before the second diaphragm renewal. They are apparently good for another year at least.

Life of the Cell: The life of the tanks is not definitely known, as some over ten years old are still in service and it is estimated that they will last twenty years. The screens last two to five years except when an accidental local electrolytic action occasionally causes a local hole that would cost more to repair than the cost of a new screen. The asbestos diaphragms are put in new every six to eight months when the cells are washed out. The new process anodes give efficient service for two to three years. The life of the other miscellaneous parts is largely dependent upon the care with which they are handled and operated.

Floor Space: Allowing ample aisles, the production of chlorine per square foot of floor space per 24 hours is about 2½ lb. A high floor space factor means a saving in installation of piping, bus-bars, etc., per unit of output.

Attendance: With cells provided with the automatic feed controls, one attendant is ample for two hundred. At the plant of the Warner-Klipstein Chemical Co., South Charleston, W. Va., there is only one attendant for 480 cells.

Quality of the Chlorine Gas: As previously mentioned, this cell was specially developed to produce relatively pure chlorine gas for the manufacture of chemicals. How successfully this was accomplished may be judged from the fact that large groups of cells have been run for periods of several weeks with the gas analyzing 99.5 to 99.8 per cent Cl and have been operated continuously producing gas averaging 99 per cent pure. Only ordinary precautions are required to keep the gas substantially free from air, without permitting the escape of chlorine gas into the atmosphere of the cell room.

FIG. 3. ORDINARY ELECTRODES AFTER 12 MONTHS' SERVICE

Quality of the Caustic: A considerable amount of undecomposed salt of course passes into the caustic liquor from all diaphragm cells, but this is readily removed in the evaporator. Far more serious is the presence of chlorates or hypochlorites. In spite of the high temperature at which these cells operate, chlorates are not found in the caustic and it is very rarely that hypochlorites can be detected. The surest hypochlorite indicator is the life of the tubes in the evaporator, even small amounts of hypochlorite greatly shortening the life of the tubes. In some caustic plants this is a serious problem, but with this cell a life of two years is not uncommon.

Efficiency: Theoretically 1000 amp. require 115 lb. of NaCl and should produce 69.86 lb. Cl and 78.67 lb. NaOH. Plant records actually show about 90 per cent ampere efficiency and 60 per cent energy efficiency.

The energy efficiency is the important figure. Several commercial cells operate, or claim to operate, at higher ampere efficiencies than the Nelson cell, but the gain is wholly illusory if the energy efficiency drops to 55 per cent at the same time. In one case the energy consumed is 1.53 kw.-hr. per 1 lb. of Cl, and in the other case 1.67 kw.-hr. are required, even though the ampere efficiency was 5 per cent better. This means a saving of nearly 5c. per cell per day, or about \$4,000 per year in a plant producing 6 to 7 tons chlorine per day, assuming power to cost \$0.005 per kilowatt-hour.

The operating data over a long period at one plant gave an average voltage drop of 3.7 volts per cell over a period of six months, varying from 3.5 to 3.8 volts. The high average energy efficiency is due to the fact

FIG. 4. TREATED ELECTRODES AFTER 18 MONTHS' SERVICE

that the cells start at a very low voltage which remains almost constant up to the end of the operating period.

Assuming that 2.3 is the correct factor for the theoretical decomposition voltage of NaCl in a water solution, the energy efficiency at 3.7 volts is 62 per cent and at 3.5 volts is over 65 per cent.

CONCLUSION

It is not claimed that absolute perfection has yet been obtained, but it is believed that this cell has reached a stage where experiment and abstract theory are things of the past. It is now a fully developed "machine" for manufacturing chlorine gas, that a chemical manufacturer can purchase as he would a filter press, a still, an evaporator or any other piece of standard chemical engineering equipment, and be assured of a fixed regular output of high quality, produced in a moderate costing, efficiently operating plant, which can be operated with ordinary labor with economical operating costs and repairs.

The author wishes to acknowledge the assistance of Mr. Nelson, who supplied some of the data and the illustrations for this paper, and also to thank the Warner Chemical Co. for the release of data and information.

Water-Resistant Glues

By F. L. BROWNE

UNTIL comparatively recently, practically all glues used in joining wood were the more or less impure forms of gelatin obtained by extraction from waste animal products such as hides, skins, bones, horns, hoofs, fish parts, etc. These glues are either of the solid or liquid type. For use the former are soaked in the proper amount of water, heated to a temperature slightly above their melting point, and applied to the surfaces to be joined, which are then put under pressure. On cooling and drying the glue film gives a strong joint. Liquid glues are applied cold and harden in the joint on drying.

Although gelatin glues of good quality yield very strong joints, they are subject to the disadvantage of softening to the extent of losing their holding power when kept in contact with much moisture, whether in the form of water or of high atmospheric humidity. Attempts have been made to increase the water resistance of gelatin glues by the addition of certain chemicals, but, although some progress has been made, satisfactory results have not yet been obtained. The only way so far found to make such joints serviceable under humid conditions is to keep the water away from them by using waterproof coatings.

The vegetable glues, made by heating starch (chiefly cassava starch) and water, in the presence of alkali lose their strength as gelatin glues do when exposed to humid conditions and can be made waterproof only by means of protective coatings.

Glued joints in an aeroplane are frequently subjected to very severe moisture conditions, and hence water-resistance is usually a large factor in the choice of an aeroplane glue. The known high strength and dependability of gelatin glues made it advisable to use them for propeller construction rather than glues whose characteristics were not so well known, especially since it was found possible to apply waterproof coatings. But for many plywood parts of aeroplanes, waterproof coating is not practicable, so that the use of water-resistant glue becomes a necessity.

At present there are two types of these in use, one having casein as a base and the other blood albumin. These glues are water-resistant in the sense that the amount of water the dry glue films on the joints will take up is limited and the saturated glue still has sufficient strength to hold the joined surfaces together.

In order to control properly the quality of plywood glued with water-resistant glues and to develop glue production it was necessary for the Bureau of Aircraft Production to know how to make and use these glues. The Forest Products Laboratory of the U. S. Forest Service was therefore requested to investigate the subject. Research work was started late in 1917 and is still being continued. The following information is based on the results thus far obtained:

BLOOD ALBUMIN GLUE

Blood glues are a very recent development, in this country at least. The few plants using them before the war had their own secret formulas, and there has been very little information published on the subject.

Water-resistant glue can be made from fresh blood and where a supply is readily obtainable from a nearby slaughter house this may be the cheapest way to make

HOT PRESS FOR MAKING EXPERIMENTAL PANELS WITH BLOOD GLUE

it. The desirability and convenience of using the fresh blood, however, are open to question. Blood is subject to rapid bacterial decomposition, and hence where it cannot be utilized at once, it must be treated with a preservative or processed and the dried blood albumin used.

The material ordinarily used for making blood glue is the black soluble albumin which remains after subjecting blood to a process for removing the fibrin and part of the hæmoglobin or red corpuscles, and carefully evaporating to dryness. This material is not only cheaper than the albumin from which all hæmoglobin has been removed, but has been found to give a stronger glue. It is stable over a reasonably long period of time, but the solubility gradually decreases with age. Since only the soluble portion of the albumin forms

the essential glue-making material, freshly dried blood is more desirable. Loss of solubility likewise makes it impracticable to prepare blood albumin glue in the form of a dry powder ready for mixing with water.

HARDENING BLOOD GLUE

Blood glue must be hardened by heating it to a temperature at which the albumin coagulates. This effect is ordinarily accomplished by the use of a hot press. The press commonly used is of the hydraulic type with hollow platens heated by steam. Blood glue is chiefly suited to plywood manufacture. Heavier joint work can be carried out, however, by clamping together the glued surfaces and subsequently placing them in a dry kiln or chamber at the proper temperature until the blood is coagulated.

Albumin coagulates at temperatures above 162 deg. F., but a temperature of about 212 deg. F. is usually employed in the press. For glues containing much inert material, temperatures as high as 300 deg. F. are sometimes used, but blisters are likely to result. A satisfactory pressure is about 150 lb. per sq.in. The time required for pressing depends upon the thickness of the outer plies; the thicker the plies the longer it takes for the heat to penetrate the wood and coagulate the glue. For $\frac{3}{4}$ -in. 3-ply material, $3\frac{1}{2}$ to 4 min. at 212 deg. F. are sufficient. The action of blood glue in hardening is the same as that which takes place in the white of an egg on boiling.

WATERPROOF GLUE

A waterproof glue can be made simply by dissolving blood albumin in water. The glue is improved, however, by the addition of a little ammonia and lime, and may be cheapened without great loss in strength by the addition of other ingredients. Too much lime must not be used, since it causes the mixture to set quickly to an unworkable jelly.

MIXER FOR CASEIN GLUES

MECHANICAL GLUE SPREADER IN OPERATION

A very satisfactory blood glue¹ is made by soaking six parts of black blood albumin in eleven parts of water for at least 2 hr., then stirring and passing the mixture through a 30-mesh screen to remove undissolved particles. One-fourth part of ammonium hydroxide solution (specific gravity 0.90) and 0.18 part of hydrated lime are then stirred in. The lime is added in the form of a thick cream made by mixing the powder with a little water.

CASEIN GLUE

Casein glues seem to have been known for a much longer time than blood glues, especially in Europe, but have not found any great use, so far as is known, until the last few years. During the war they have been used in American, British, French, Italian and German aeroplanes. Much more information is available in the chemical literature and old patents on this subject than is the case with blood glue.

Casein is a by-product of the dairy industry, obtained either from buttermilk or skim milk. Most of it comes from skim milk. The casein is precipitated by adding rennet, or acids, such as sulphuric or hydrochloric, or by allowing the milk to sour naturally, forming lactic acid from the milk sugar. There are many slight variations in the technique of the processes, so that the product obtained on the market is not uniform, the chief variation being in the ash content and the acidity. This variation frequently makes necessary slight changes in proportions in using different shipments of casein in a given glue formula.

Casein is very closely related chemically to albumin. It does not show such definite coagulation on heating; as in the case of albumin, however, certain chemicals have the property of causing its solutions to harden, forming jellies. Some of the casein jellies after drying will absorb only a limited amount of water. Casein glue is mixed at ordinary temperatures and the joints are pressed without heat until the glue has hardened, then they are dried down to the moisture content desired in the finished product.

¹Government patent in the name of S. B. Henning, East Products Laboratory, applied for.

Casein glues may be divided into two classes: (1) "Wet" glues, in which the various ingredients are kept separate until the glue batch is to be made up for immediate use; and (2) "dry" glues, in which all the ingredients except the water are mixed to form a dry powder which can be kept until ready to use and then merely mixed with water.

A very simple but effective wet glue can be made using simply lime and casein, but it is open to the serious objection that its working "life" is only from 15 to 45 minutes. At the end of this time it has hardened to an unworkable jelly. The following formula for a wet glue has given very excellent results:*

100 parts casein	} Soak 15 minutes	} mix	} mix
130-280 parts water			
15-22 parts hydrated lime			
90 parts water			
70 parts sodium silicate (water glass)			

The casein is soaked in the water until thoroughly wet, the lime water is stirred in, and the sodium silicate added last. Stirring is continued until a smooth mixture, free from lumps, is obtained. The amount of water in which the casein is soaked as well as the quantity of lime used depend upon the composition of the casein, particularly upon its ash content. The life of this glue is usually about 8 hours.

In mixing dry glues, the powder is stirred into the proper amount of water until a smooth liquid results. With all casein glues, it is important that the mixing be done thoroughly so that the casein will be completely dissolved and the glue free from lumps. For the purpose a power cake mixer has been found to give very satisfactory results.

COMPARISON OF BLOOD AND CASEIN GLUES

Blood glue has the disadvantage, as compared with casein glue, of requiring hot pressing, which limits the output of the press and makes it less easily used for such joint work as gluing propeller laminations. Blood glue is not readily obtainable as a dry glue, whereas casein is. Casein glue has been somewhat less expensive, but a considerable amount of cheap inert matter can be introduced in blood glue without serious loss of strength. In the matter of water-resistance, blood glue possesses a slight advantage. Although blood and casein glues are more expensive than vegetable glue, their water-resistance will give them a wide application in the future. They are both in the early stages of development still, and much improvement in both cheapness and water-resistance may be looked for.

Tennessee Copper Co. to Enter Fertilizer Field

At present all of the sulphuric acid produced by the Tennessee Copper Co., amounting to about 360,000 tons of 50-degree acid annually, is being delivered to the International Agricultural Chemical Co. at the old contract price of \$4.81 a ton. At the expiration of that contract in December, 1920, the company will manufacture acid phosphate and, since the acid plant is the largest in the world, it will undoubtedly become one of the leaders in the fertilizer field. Phosphate rock will be obtained from the extensive deposits of the Stuart-Memminger interests in Polk County, Florida, which have been purchased recently by the Tennessee Copper & Chemical Corp. The tonnage of rock already proved in these properties will take care of the company's requirements for a long time to come.

*For a description of the acid plant see CHEM. & MET. ENG., Vol. XIX, p. 404.

Carbide Conversion Calculations

BY ISMOND E. KNAPP

IN CARRYING on experimental work in connection with the manufacture of calcium carbide, considerable time was consumed in making the necessary calculations. Changes were being made in the design of the furnace, and it was important to know the efficiency of conversion that was obtained in each run. Inasmuch as the quality of the coke and lime varied considerably, this calculation was rather tedious. In order to simplify it, the following method was worked out, and it has proved entirely satisfactory.

The reaction may be represented by this equation:

Analysis shows that the crude carbide or furnace product contains only a small amount of free carbon (seldom over 1.0 per cent) and but very little sulphur. These small amounts are neglected in these calculations, and it assumed also that all of the constituents in the coke ash and the impurities in the lime (such as SiO_2) go through the carbide furnace unchanged, and are present in the furnace product. On this basis the furnace product will have only the following constituents:

- (1) Calcium carbide.
- (2) Coke ash.
- (3) Lime impurities.
- (4) Unchanged lime.

Let A = decimal fraction fixed carbon in the coke.

B = decimal fraction ash in the coke.

C = decimal fraction CaO in the lime.

D = decimal fraction loss on ignition of the lime.

Then, $1 - A - B$ = moisture + volatile + sulphur in the coke and $1 - C - D$ = impurities in the lime.

It is evident from the above equation that the theoretically correct proportions for a mixture of lime and coke are:

$$\frac{36}{A} : \frac{56}{C}$$

In case the proportions actually used are not the theoretical, care must be taken that they are calculated to the above form, and that only the factor 36 is affected. For instance, if a small excess of carbon were used, this factor might become 37 or 38. It can be determined easily by solving this proportion:

$$\begin{array}{l} \text{lb. lime used} \times C = 56 \\ \text{lb. coke used} \times A = X \end{array}$$

whence, X = the factor to be used in place of 36 in all of the following formulae.

Assuming that the efficiency of conversion, E , is known, then the weight of CaC_2 in the furnace product from a coke-lime mixture of the above composition will be $64E$. The weight of the coke ash will be $\frac{36}{A}B$; the weight of the impurities from the lime will be $\frac{56}{C}(1 - C - D)$; and the weight of the unchanged lime will be $(1 - E)56$. The corresponding amount of unchanged carbon, $(1 - E)36$, apparently is burned, and so does not appear in the furnace product. Now, if F re-

sents the total weight of the furnace product, we may write:

F = carbide + ash + dead lime + excess lime

$$64E + \frac{36B}{A} + \frac{56(1 - C - D)}{C} + (1 - E)56 \quad (I)$$

The purity of the furnace product, P , is of course the ratio of the weight of CaC_2 in the furnace product to the total weight of the furnace product, i.e.,

$$P = \frac{64E}{F}$$

or, substituting the above expression for F ,

$$P = \frac{64E}{64E + \frac{36B}{A} + \frac{56(1 - C - D)}{C} + (1 - E)56}$$

By rearranging this equation we finally obtain:

$$E = \frac{P \left(\frac{36B}{A} + \frac{56(1 - C - D)}{C} + 56 \right)}{64 - 8P} \quad (II)$$

A and B are known from the coke analysis; C and D are known from the lime analysis; and P is known from the analysis of the crude carbide. Hence the efficiency of conversion can be calculated quickly by simple substitution.

The following example will show the practical application of the foregoing formula:

Data:

Coke analysis: 0.903 fixed carbon, 0.069 ash.

Lime analysis: 0.768 CaO , 0.177 loss on ignition.

Mixture ratio: 200 lb. lime to 130 lb. coke.

Charged into furnace: 766 lb. of above mixture.

Recovery: 459 lb. crude carbide.

Analysis of product: 0.076 CaC_2 .

Calculations:

$$\frac{200 \times .768}{130 \times .903} = \frac{56}{X}, \text{ whence } X = 36.3$$

Then the proportions in the mixture are $\frac{36.3}{A} : \frac{56}{C}$

$A = 0.903$; $B = 0.069$; $C = 0.768$; $D = 0.177$; $P = 0.760$.

Then by formula II, $E = 0.824$ or 82.4 per cent efficiency of conversion.

As a check on the above calculation it is often of interest to go back and calculate the weight of the furnace product, using formula I for F . The result thus obtained should show a fairly close agreement with the weight of furnace product actually obtained. The writer has checked repeatedly within 3 per cent in this manner.

For instance, in the example given above, the weight of the charge can be computed thus:

$$\frac{36.3}{A} = \frac{56}{C} \quad \frac{36.3}{0.903} = \frac{56}{0.768} = 113.1$$

By formula I, $F = 69.4$.

The weight of the charge actually used was 766 lb.

Hence, $113.1 : 69.4 :: 766 : X$.

Whence, $X = 470$ lb. theoretical weight of the furnace product. This result shows a variation from the weight of the crude carbide actually obtained (459 lb.) of 2.3 per cent.

Sometimes it is desirable to know the maximum purity of the crude carbide that can be obtained from given raw materials, with an efficiency of conversion of 100 per cent. This can be found by putting $E = 1$

in the above formula for P , which then reduces to

$$P_{max} = \frac{64 \times 1}{64 + \frac{36B}{A} + \frac{56(1-C-D)}{C}}$$

In the example given above the maximum purity obtainable is 90.4 per cent.

Although a high degree of accuracy is not claimed for these formulae on account of the assumptions made regarding the chemical changes in the carbide reaction, nevertheless they have proved very helpful in the work for which they were developed.

Wilmington, Del.

The Photographing of Etched Sections of Steel Forgings at Low Magnifications*

BY FRANCIS B. FOLEY
Metallurgist, Bureau of Mines

IT IS frequently found desirable to examine certain coarse-grained steel, for example steel in the forged condition, under low power for the purpose of getting a better comparison of grain size than is usually brought out in examining such steel by the microscope at magnifications of 50 diameters and higher. The desirability of low-power examinations of forgings became evident in recent investigations by the Bureau of Mines, where a grain size was found under the microscope which was difficult to record by photographing because the field covered by the microscope was too restricted, very often not sufficiently large to take in a single grain. An effort was therefore made to find a method of

INSTRUMENTAL SETUP FOR PHOTOGRAPHING CROSS-SECTION OF TEST PIECE

photographing a large area of the etched section without losing the relative value of the microconstituents. The apparatus that resulted was cheap and crude, but productive of excellent results, as may be observed in the accompanying illustrations, and, while the method adopted was not remarkable for its originality, it seems worthy of description and attention, since it appears that the photographing of etched specimens of steel at magnifications as low as 7 diameters by vertical illumination has not been practiced to any extent, at least not to the writer's knowledge.

The apparatus with a specimen in place for photographing is shown in the half-tone illustration in this column. The illuminator should be of optically flat glass or glass in which there are no undulations which will interfere with the proper refraction of the

light rays or with the focusing of the image. The illuminator used in taking the photographs shown in Figs. 1, 2, 3, 4, 5 and 6 was a small lantern slide from which the emulsion had been removed. A fairly bright, well diffused light is desirable and, in this connection, a ground glass diffusing screen is of considerable help. The light in the stereoscopic lantern shown in the illustration is a 110-v. 400-w. lamp. The exposures, without a ground glass screen, were of 30 to 45 seconds duration.

The remarkable variation which can be brought about in the condition of forged steel by improper or lack of temperature control stands out prominently when the large field which it is possible to cover at low magnification is offered for study. Fig. 1 represents the

PLAN OF APPARATUS

structure of a bar taken from an untreated forging, which, without heat treatment, gave an elongation of 18 per cent, and Fig. 2 the structure of a bar from the other end of the same forging, which gave an elongation of but 5 per cent. Were the entire forging in the condition represented by Fig. 1 a very simple heat treatment would suffice to put it in the best condition, but the condition shown in Fig. 2 makes it necessary to go to much greater trouble and expense to bring about a desirable structure. The platy arrangement of the ferrite in Fig. 6 is brought out to a better advantage in the 7-diameter magnification shown here than it could be in a small area at high power. The composition of the steel shown in this photograph was unusual only in sulphur, which was 0.05 per cent, whereas the usual product ran sulphur below 0.03 per cent. Figs. 1, 2, 3, 4, 5 and 6 do not represent specially selected forgings or structures which have been produced in a predetermined manner, but random selections from forgings put through the usual course of manufacture at the plant where the forgings were made. All are of 3 per cent nickel gun steel of 0.35 to 0.40 per cent carbon and have had no heat treatment subsequent to the forging operation and serve well to show the wide variation in structure which heat treatment is called upon to correct.

Etching for photographing in the manner described here has been done with the usual picric acid reagent, but the etching has been carried deeper than is usually done for ordinary microscopic examination. The pearlite areas are etched quite dark, but if the specimen is thoroughly washed in water after etching, preferably under a running stream, and then dried, the structure developed is very good for examination at high power in spite of the very deep etch.

*Published by permission of the Director of the U. S. Bureau of Mines.

Exposure Tests of Sheeting Material

Description of the Standard Sheeting Tested and Method Followed—Results Graphically Charted—
Conclusion: The Best Sheeting Material Is a Copper Bearing Steel With 0.20
to 0.25 Per Cent Copper

By SAMUEL L. HOYT, E.M., PH.D.

Associate Professor of Metallurgy, University of Minnesota, Minneapolis, Minn.

FOR the past three years the writer has been conducting exposure tests of sheeting material with the object of ascertaining the relative behavior of various standard commercial products such as the bessemer and open-hearth sheets, pure open-hearth iron sheets, and copper-bearing steel sheets. The sheets used were obtained from various manufacturers in this country and were supposed to represent typical commercial grades of these materials. As far as is known, there is no reason to believe that they were other than as represented.

The test specimens were exposed continuously to the rain, snow and sunshine, in amounts which are shown by the curves in Fig. 1, which were plotted according to the data kindly furnished by Mr. U. G. Purssell of the United States Weather Bureau, Minneapolis Station.

The test specimens, taken from each sheet submitted, were placed in a rack on the roof of the School of Mines building on the campus of the University of Minnesota. The air is comparatively pure, the only contamination being from a railroad passing through the campus on which the service is infrequent, and from two power plants situated on the campus some distance away from the place of the tests.

MATERIAL USED

Requests were made of leading producers to submit sheets of their standard sheeting one yard square and in the condition in which they left the mill. These sheets came in both 20-gage and 26-gage. The compositions of these materials are given in Table I.

TABLE I. CHEMICAL ANALYSIS OF SHEETS

CONDUCT OF THE TESTS

From each sheet submitted were cut a number of small specimens $1\frac{1}{2} \times 3\frac{1}{2}$ in., and marked for identification according to Table I. These specimens in their natural condition were then weighed and placed in a rack on the roof of the School of Mines building. The specimens were arranged in rows numbered from I to X inclusive, each row containing one sample from each sheet submitted. At the end of the first period only the

specimens in the first row were taken down and the remaining specimens were not touched. After cleaning off the rust and weighing, the I specimens were replaced in their proper position in the rack. At the end of the second period the first two rows, or the I's and II's, were taken down and cleaned and weighed and then returned to the rack. This procedure was continued so that at the end of each period another additional row of specimens was taken down along with all those which had previously been taken down and cleaned and weighed and, in turn, all returned to their places in the rack. At the end of the tenth period the number X's were taken down for the first time, so that they had

FIG. 1. WEATHER CONDITIONS DURING TEST

been exposed continuously, that is, without intermediate cleanings, for the entire period of three years. In this way the effect of leaving the rust coating on as well as of removing it could be ascertained.

RATE OF CORROSION

The rate of corrosion was determined by noting the difference in weight before exposure and after removing the rust film. The loss in weight represented that portion of the specimen which had rusted or corroded over the corresponding time interval. The method used to remove the rust was that of treating in hot ammonium citrate, which as far as could be observed gave entirely satisfactory and comparable results. Other corroborative evidence of the rate of corrosion was obtained from the total failure of the specimens and their general appearance.

FIG. 2. WEIGHT LOSS: 20-GAGE, NO. 1 SAMPLES

The idea underlying this test was to secure a reliable index to the rate of corrosion, and by treating all the specimens exactly alike to determine the relative corrosion of the various materials submitted for the tests. The agreement between "loss in weight" determinations and the absolute failure of certain materials on the one hand, and the tenacious resistance to corrosion of other materials on the other hand, has given the writer complete confidence in the index of corrosion furnished by the data which are presented here.

PRESENTATION OF RESULTS

First of all it should be stated that no conflicting or contradictory data have been secured, to the writer's knowledge, to cast doubt upon the general validity of the results; consequently it is held that it is not neces-

FIG. 3. WEIGHT LOSS: 26-GAGE, NO. 1 SAMPLES

sary at this place to reproduce all the data obtained or all the curves which have been plotted, and hence only certain selected data are here reproduced in Figs. 2 to 7.

Fig. 2 represents the loss in weight in grams of the 20-gage, No. 1 specimens. It will be remembered that these specimens were cleaned at the end of each exposure period, these periods being at the end of 1, 3½, 5, 7, 9, 12, 15, 18, 24 and 36 months respectively. The order

FIG. 4. RATE OF CORROSION UNDER CONTINUOUS EXPOSURE; 20-GAGE

of excellence of the materials represented by this test is 29b, 29a, 41, 37, 45, 43, 25, 33 and 33a. It will be noted that the 20-gage specimens were still intact at the end of three years' exposure.

Fig. 3 represents the same tests on the 26-gage specimens. The 35's failed completely at the end of 15

FIG. 5. RATE OF CORROSION UNDER CONTINUOUS EXPOSURE; 26-GAGE

months. The 26, 44 and 46 failed between 18 and 24 months, and the 38 and 42 failed completely at the end of 24 months, while the only specimens which were still intact at the end of 36 months were the 31's. These specimens were just about as good as gone, so that the loss in weight is taken as the total or original weight. The order of excellence is 31a, 31, 42, 38, 26, 44, 46, 35, 35a.

Fig. 4 is intended to show the rate of corrosion under continuous exposure, that is, without removing the rust film at the end of each period. It was necessary to take

a new specimen for each period represented so that the I specimen was taken at the end of the first period, and II at the end of the second period, the III at the end of the third period, and so on up to the X specimen at the end of the three years. It is hardly to be expected that these curves will show as uniform results as the I's or the II's or the III's, etc., plotted separately. The rate of corrosion in this case is appreciably less because the protective coating of rust is allowed to remain on the specimens for the full time for each period. The order of excellence of the 20-gage specimens in this series taken at the end of 36 months is 29b, 29a, 43, 41, 25, 33, 45, 33a.

Fig. 5 corresponds to Fig. 4 except that it represents the 26-gage sheets. Here again it will be noticed that certain of the specimens failed prior to 36 months. Samples 35 and 35a failed at the end of 15 months. The order of excellence of the specimens in this test is 31a, 31, 42, 44, 26, 46, 35a, 35.

In order to compare the relative resistance to corrosion of copper-bearing steel, pure open-hearth iron and plain steel, the various specimens were divided into these three classes and the average loss in the weight for each class calculated. The results obtained for the number I specimens are shown in Fig. 6, in which both gages are represented. The order of excellence, which remained the same for the entire period, is copper-bearing steel, pure iron, and plain steel.

Fig. 7 represents the average losses of these three types of materials at the end of each period in case the protective coating was allowed to remain on for the total time up to the end of the period. Here again slight

FIG. 6. RELATIVE RESISTANCE TO CORROSION; RUST REMOVED PERIODICALLY

irregularities may be noticed, but the same order of excellence is obtained, and this remains the same throughout the entire 36-month period. It is as before, copper-bearing steel, pure iron, and plain steel.

CONCLUSIONS

The general conclusion which, it is believed, may be drawn from this exposure test is that the so-called copper-bearing steel, in which the copper content is about 0.20 to 0.25 per cent, offers the greatest resistance to corrosion of the common sheeting materials. After

copper-bearing steel come pure open-hearth iron, open-hearth steel and bessemer steel in the order of excellence. As evidence of this fact we have the loss in weight, the ultimate failure of the materials and their general appearance both before and after removing the rust-coating. It was noted that while the copper-bearing

FIG. 7. RELATIVE RESISTANCE TO CORROSION; CONTINUOUS EXPOSURE

steel, as compared to the other materials, has a particularly dense protective coating of rust, the material itself has an abnormally low tendency to oxidize in moist air. On this account it is not sufficient to explain its resistance to atmospheric corrosion as being due primarily to the nature of the rust-coating. A more plausible explanation seems to be that the copper, by entering into solid solution in the iron, lowers the solution pressure of the iron. The physical character of the rust-coating may be merely a manifestation of the rate at which the coating is formed.

The two best sheeting materials, according to this test, are copper-bearing steel and pure iron. Aside from the superiority of the former, it may be of interest to note that, from the metallurgical point of view, it is both cheaper and more economical of time and materials to produce copper-bearing steel, as compared to pure iron. Thus heats of copper-bearing steel can be made according to standard practice and in standard time with a final addition of about a dollar's worth of copper per ton of steel. Pure iron, on the other hand, is a difficult product to make on a large commercial scale and requires high temperatures and something like 20 to 24 hr. per heat. Both as regards resistance to atmospheric corrosion and cost of production, copper-bearing steel seems to possess a decided advantage over pure open-hearth iron as a sheeting material.

Japanese Developing Steel Industry

The American Chamber of Commerce in London understands that a British naval correspondent in Japan foresees the end of Japan's dependence on steel imported from the United States and Great Britain. The Japanese are said to be exploiting on a large scale the ores which they have discovered in Korea and to be making extensions of their industries to handle this new source of supply. Ore concessions in China will further increase the Japanese raw material. This British correspondent predicts not only that Japan will soon be independent of outside sources of supply but that in another 10 years' time she will be exporting cheap steel to the Pacific markets.

Flakes in Alloy Steel

A Recapitulation and Discussion of Recently Published Matter About This Balling Defect Appearing in Gun Tubes and Other Large Forgings of Alloy Steels—There Are Probably Two Kinds of Real Flakes, but Only One Kind Which Is Dangerous

By ERNEST EDGAR THUM

TWO years ago an enormous expansion in our ordnance program caused many concerns to produce large alloy-steel ingots and forgings—a class of output entirely new to them. As an instance, high-strength gun tubes were needed in great numbers, to the most exacting specifications, requiring test bars cut at right angles to the axis. Immediately there appeared bright silvery areas in otherwise normal test bar fractures, associated with low and variable elongation and contraction in area, causing rejection of a tremendous tonnage even though the elastic limit was unaffected and the ultimate strength lowered but slightly. Failure of more than half the production to pass acceptance tests caused earnest inquiry on many sides, despite the fact that many production-mad concerns profited as much from bad forgings as from good.

Coarse crystalline areas in fine crystalline breaks have been noted before—indeed, can be produced at will by straining a portion of sound metal to a critical point, followed by continued annealing below recalcence. But the defects in question appear to have little depth; the so-called flake often exhibited warped surfaces such as the rounded corners and ends of squeezed macro-crystals. Numerous names were given them, they seemed to occur at different stages in the history of the piece, from a wide variety of causes, and the whole situation was fraught with the most extreme confusion. Most investigators now agree, however, that a flake results from a series of intercrystalline cracks, produced by stresses set up in the metal by its treatment, the location being determined by points of weakness already existing; in other words, a flaky steel contains a series of internal "bursts" in heterogeneous metal. Homogeneity is the obvious remedy; given sound ingots and barring amateurish forging and heat treatment or rough handling, a piece free of this defect should result. Actually this was the case; fewer and fewer rejections came with continued experience.

EXISTENCE OF TWO KINDS OF FLAKES

If, then, a flake is an intercrystalline crack, does it exist as a crack in the metal during and after its fabrication, or is it a plane of weakness which spreads from a minute parting only on stress? Probably both. The evidence suggests that there are two kinds of flakes; the one due to actual cracks in clean metal and the other to inclusion films. Large cracks pre-existing in a test piece will evidence themselves by correspondingly low values for elastic limit and ultimate; eliminating from this discussion, however, the unwelded tears due to unreasonable reduction and rough handling, a true flake is something which does not lower the elastic limit of the test piece materially. But take a good ingot, saw through it parallel to the base and polish this new section. Without any etching will appear short hair-

lines in the polished surface, doubtless traces of actual partings.

Such tiny cracks have a habit somewhat depending upon the shape of the ingot; probably they are due to stresses thrown into the shrinking metal as it cools through the tender heat just below recalcence; the exact nature of these stresses is somewhat obscure, however, and a variety of opinion exists. However, in a given heat, such flakes will appear independently of the size, shape and method of pouring; being deep seated, they may be welded shut if high-temperature forging is sufficiently penetrating and the burst contains no oxidized inclusions. Clean small cracks in the ingot should thus constitute no insurmountable defect in the metal. Ultimately they may be due to a certain homogeneity in the metal, and are thus closely related to flakes due to inclusion films, although in the former case the heterogeneity may be a normal incident of perfectly well-made metal.

Rawden, however, finds a very thin film of slag at the ends of flakes in forged tubes. This inclusion evidently permits the original separation and later prevents proper welding, as well as forming an internal notch inducing premature failure under stress. Other observers also note evidence of slag in flaky fractures, and describe flakes as a recrudescence of local crystalline fractures due to the presence of slag—known for some time. Metal in contact with such slag inclusions generally shows a structural change—usually a decarburization—and such spots may well provide the nuclei from which fracture starts. On the other hand much "dirty" steel containing large quantities of solid non-metallic impurities is not flaky, while many observers are positive that slag particles of microscopic size are not universally present in flakes.

WHAT CAUSES FLAKES

While it is a favorite method to ascribe visible effects to invisible causes, there is much to fortify the belief that flaky test bars are ultimately due to inclusions of oxidized material at the original grain boundaries, sometimes indistinguishable from tenuity, dispersity or lack of optical differentiation, but nevertheless persisting since the metal left the furnace or introduced by subsequent overheating. As such they prevent normal adhesion at the original grain boundaries, and while no extensive burst or crack may exist in the finished piece at such areas, as soon as the surrounding metal is stressed beyond its elastic limit, these brittle planes of weakness give way first, the fracture typical of a "flake" simulating the original but now deformed coarse-crystalline boundaries. Localized stresses then extend the fracture to failure with little contraction in area, typical of "notched" bars.

On this basis, flakes are caused by faulty furnace

practice. They tend to run by heats, yet their occurrence is so variable that they are not due to any particular metallurgical practice or to any chemical composition—they are found in converter, basic and acid open-hearth and electric steels, and while giving most trouble in tender alloy steels (possibly due to their viscosity or crystalline habit) they have been found in common carbon steels when pulled transversely to the direction of working. Yet the flakiest steels have been produced on this side from the use of rusty turnings, light scrap, or excessive ore, or from stopping the boil, or casting insufficiently worked metal, and the defect has been largely eliminated by approximating the successful European practice of using only the purest materials, melted under a reducing flame, and worked with a minimum of iron ore. Whether like practice will eliminate the dangerous "gashes" and "fissures" in rail steel depends upon the moot question as to whether these defects are due to flakes in metal or to tearing the structure of excessive reduction in rolling.

Thus the higher oxides of iron trapped within the steel even in minutest particles seem to be the real culprits responsible for flakes; large quantities of a neutral slag will not cause like bad effects. As Giolitti points out, a tiny bit of oxidized material will so disturb the equilibrium existing in normal steel among ferrite, cementite and two carbonoxides that an excess of CO₂ will be formed, causing a local decarbonization and a thin border of ferrite on the surface of the original dendrites. This white ferrite—probably embrittled by other segregated impurities—is the plane of parting, and upon stressing produces the silvery, coarse-crystalline "flake." On such a basis it is evident that overheating before forging will cause flakes simply by the formation of "burned" spots where oxygen has penetrated into the liquid grain boundaries of otherwise sound metal. Again, flakes have formed on deep-seated carburization of what seemed to be perfect ball-races. Here an oxidized impurity caused a sharp variation in carbon concentration, and on hardening induced internal bursts by a mechanism exactly similar to that of exfoliation.

HOW TO ELIMINATE THE DEFECT

There yet remains to be explained, however, why there is no particular microscopic appearance associated with flakes other than a markedly non-homogeneous structure such as elongated dendrites, banded regions of excess ferrite or small grains. In other words, flakes often show no ferrite borders under the microscope, and grain refinement may exist up to the parting itself. But it should be remembered that the amount of excess ferrite induced by a tiny, almost invisible, inclusion is likely to be little more than the thinnest shell, which under proper heat treatment will quickly diffuse back into the sound metal. Heat treatment must be long continued, however, to allow slow-diffusing impurities to migrate away from their location, and to exhaust permanently the decarbonizing potentialities of a bit of oxide. Nor can it obliterate an internal crack any more than it can refine the grain of an exposed break—grain refinement occurs only up to the parting plane. In such cases the apparent crystallinity of a flake in hardened steel is a surface configuration only, but in fact persisting since the original crystallization of the ingot.

If the above analysis of the situation is correct, it is evident that the best way to eliminate flakes due either to

cracks in ingots or to included films is by careful metallurgical practice, starting with the selection of proper charge components, continuing through melting, refining and casting stages into the mechanical reduction processes and heat treatment even up to the final anneal to release hardening strains, for flakes have appeared in all these stages.

It is idle to say that Americans cannot follow European methods and use purest raw materials, or that the way to eliminate flakes in nickel steel is to leave out the nickel. Sound alloy steel of high strength can be made if every energy be turned toward quality rather than quantity—a practice Americans like to talk about but seldom think expedient to put into practice. Should flakes appear in the ingot, it is doubtless best to scrap the ingot before spending a great deal of labor to make it into a forging, then only to be rejected.

Flaking in small degree may be cured, not by cutting more and more test bars until a good one is found, but by heavy reduction to knead the original structure and long annealing to allow the complete diffusion of soluble segregates. Mechanical reduction processes at correct welding temperatures and by moderate stages are obviously the most important factor in closing permanently clean and open cracks; a practice which only makes good metal better. Flakes from segregates can best be warded off by eliminating segregating impurities; long carefully planned heat treatment is required for the correction of this defect appearing in minute amount. Therefore dirty metal should be scrapped.

Such observations appear to be truisms, and so well accepted by the metallurgical fraternity as not to warrant repetition, were it not for the fact that the occurrence of flakes at a time of national danger is only another illustration of what happens when careful metallurgical practice is disregarded. One cannot make good cannon out of bad ingots, but can easily make bad cannon out of good ingots.

Attorney General Interprets War Minerals Relief Act

At the request of the War Minerals Relief Commission the Attorney General has rendered an opinion interpreting Section 5 of the Relief Act which was designed to reimburse net losses sustained by persons who were "producing or preparing to produce either manganese, chrome, pyrites or tungsten in compliance with the request or demand of the Department of the Interior, the War Industries Board, the War Trade Board, the Shipping Board or the Emergency Fleet Corporation." In his opinion the Attorney General stated that "one of the five Governmental agencies must have asked (either by request or demand) the claimant to produce or to prepare to produce one of the four named minerals. The statute specifies the five agencies authorized to make request or demand for the production of minerals, specifies the minerals, and specifies that the production, or preparation for production, must have been 'in compliance with the request or demand' of one of the five agencies."

Under this interpretation it appears that those who sustained loss by producing or preparing to produce the minerals named in response to a general appeal or solicitation will not be entitled to relief under the provisions of the act.

Manufacturing Plant of the Providence Gas Co.—III*

Description of the Installation and Operation of a Battery of 40 Koppers Cross Regenerative, Combination, By-Products Ovens—Extension of the Coal and Coke Handling Apparatus—Treating of Coke Oven Gas

By WALTER M. RUSSELL

AS EARLY as 1914 the engineers of the Providence Gas Co. felt that the Dessau vertical coal gas plant should never be extended in case additional coal gas equipment was needed; in fact, it was even recommended that that plant be abandoned and a new plant of Woodall Duckham vertical retorts be built in its place. After having had an opportunity to study the Dessau vertical plant for several years, it appeared that American conditions were so very different from European conditions that a type of plant which had proved successful abroad might not be so in this country. In 1914 the vertical retort had not been developed in this country to the extent that it now has, particularly in the use of silica material and labor saving devices. Therefore, the abandonment of the vertical retort plant at Providence must not be taken as a condemnation of the system or even of this particular plant. In April, 1917, a report was made, recommending that a coal gas plant of 6,000,000 cu.ft. daily capacity be built. Careful study was made of the existing types of plants in the United States. At about this time, Mr. John R. Freeman was elected president of the gas company, and during the year 1917 also was appointed as the company's engineer. By the time Mr. Freeman had become president of the company, the growth of the business was such that any system other than bulk carbonization appeared unsuited for this plant, which eliminated from consideration even the highly successful vertical retort plants typified by the works in Rochester, N. Y. In November, 1917, after an exhaustive study of the whole situation, Mr. Freeman brought in a report, recommending the construction of a Koppers combination gas oven plant with a nominal capacity of 700 tons of coal a day, and this plan was adopted.

COMBINATION GAS AND COKE OVEN DECIDED ON

Installations of Koppers ovens at St. Louis, Mo., and the Seaboard By-Product Coke Co., Jersey City, N. J., had been serving their respective cities with a part of the gas from the carbonized coal and had demonstrated the feasibility and value of such an operation. It was considered impossible, in the case of Providence, to operate a straight coke oven plant successfully, as the volume of coke for sale per thousand cu.ft. of gas sold appeared to be excessive. In the other installation of Koppers ovens, where the gas was used for city purposes, it was the rich portion of the gas which was so distributed, the lean portion being used to heat the ovens. The first intention was to build ovens at Providence which could be operated only as producer gas fired ovens, but later this plan was changed and it was decided to build a combination gas and coke oven

which could be operated either as a gas oven or coke oven. A single collecting main only was supplied. Therefore, all of the coal gas, both the rich and the lean, is mixed at the collecting main and delivered through the plant to the storage holder. Gas can be taken from the storage holder and returned to the battery, being burned in the flues by means of the ordinary gas burners supplied with standard Koppers combination ovens. Also the ovens can be operated on producer gas. One of the reasons why this decision was arrived at was that it was intended to build a by-product producer gas plant and there were certain possibilities connected with starting up such an installation which made it advisable to have the alternative feature as a matter of safety and insurance for continuity of operation.

Also should the market for coke ever become capable of absorbing at a sufficiently high figure the entire output of the battery operating on its own gas, the water gas plant could make up the deficiency of coal gas output thereby occasioned.

DESIGN ALMOST ENTIRELY NEW

As there were no Koppers ovens operating in the United States on producer gas, it was necessary for the Koppers company to make a comparatively complete new design, particularly with reference to that part of the oven below the sole flue, including the regenerators, producer gas and fuel gas mains and passages and the apparatus for their control. Thus, this battery of ovens as it stands to-day represents something entirely distinct from any other plant yet built in the United States, but it has already demonstrated its value and justified the faith of the builders, and it will undoubtedly prove the forerunner of a series of such installations.

It was at first intended to erect a battery of producers to operate on coke breeze and small coke. These producers would probably have been of the well known Kerpely type, which has proved so successful in foreign Koppers oven installations. The writer first became associated with this project in the latter part of 1917 and brought to the attention of the company's engineers the great possibilities of the bituminous coal producer, particularly when operated on by-product recovery, citing the well known examples of such practice in England. A careful investigation of the possibilities of bituminous and by-product producers was undertaken and, after a long series of experiments, investigations and consultation with the foremost gas producer builders and producer gas engineers in the United States, a contract was finally given to the Wellman-Seaver-Morgan Co. for five producers and to the Steere Engineering Co. for the equipment for cleaning, cooling and preparing the gas for use in the ovens.

*This is the third and last part of a paper read before the American Institute of Chemical Engineers, at Cambridge, Mass., June 20, 1919. See CHEMICAL & METALLURGICAL ENGINEERING, Vol. 21, Nos. 1 and 2, pp. 34 and 35.

The Wellman-Seaver-Morgan Co.'s engineers brought out an entirely new design of gas producer intended to operate on bituminous coal, either with by-product recovery or without, depending on the depth of fuel bed and other special details. The Steere Engineering Co. proposed a gas cleaning plant similar in many details to plants which it had already put in successful operation and also including some new and novel conceptions.

Owing to changes which were made by the gas company in its plans late in 1918, it was not possible to complete the producer gas plant in time for it to be used for the first few weeks' operation of the ovens, and they were therefore started up and run for a few weeks on run of oven gas; thus demonstrating their flexibility and adaptability to widely different conditions of operation and fully justifying the expenditure for including the combination feature.

Patriotic conditions played no small part in forming the decision to adopt a coke oven plant. At the time

FIG. 20. COAL BELTS ALONGSIDE COAL DOCK AND REHANDLING PLANT

the contract was let, the United States Government was experiencing a severe shortage of foundry coke and lent considerable assistance toward the construction of this plant, with a view to taking over its entire output of coke immediately on its completion. The uses of the War Department would also have provided an outlet for its production of aqua ammonia from the coke oven gas, sulphate of ammonia from the by-product producer plant and the light oil products from the benzol plant. As the plant did not begin to turn out coke until January, 1919, the demands of the Government no longer existed and other outlets for its products are being found.

MINOR ADDITIONS TO THE WORKS

In addition to the building of a battery of ovens and the extension of the coal and coke handling apparatus and the apparatus for treating the coke oven gas, many other improvements to the plant had to be undertaken during the past year, which included the erection of a coal store for boiler coal, an administration building, a stocking or rehandling pit for railway coal, the installation of four Coxo stokers for handling inferior grades of boiler fuel, the installation of a new feed water heater and the construction of a storage battery plant to provide power for peak load demands, in addition to the regular output of the works' private power plant.

These minor additions to the works' equipment will be discussed before the description of the oven plant proper, as they were in a sense preliminary to it.

Stocking and Rehandling Pit—In years past, almost all fuel for the gas was received by boat, but disturbed transportation conditions during the year 1918 caused a great deal of all-rail coal to be brought in. Ordinarily this all-rail coal could be handled direct from the cars by means of the telfer buckets, but the above-mentioned unusual conditions made this impossible. A concrete pit was, therefore, constructed at a convenient place under the telfer lines, so that two cars of coal could be discharged by means of hopper bottoms or side dump chutes onto an inclined plane, which carried the coal into a pit directly under the telfer rail, where one or more telfer buckets could readily obtain access to it. This pit has been in constant use during the past year.

Administration Building—The development of the manufacturing department and the unusual amount of repair work during the past year for rehabilitating the plant required more extensive shops and offices than existed. In addition plans were in process of formulation for the development of by-product business and for very careful chemical control of the plant. When the Sassafra Point Works was first built, a portion of the meter house was used as an office and works laboratory, but this was entirely inadequate for the past year and was also situated at a considerable distance from the heart of the works.

It was, therefore, decided to remodel an existing building, the foundations and roof of which lent themselves to such a project. A brick building was, therefore, constructed, containing basement, first and second floors, which is 144 ft. long and 40 ft. wide with an ell 31 ft. wide and 144 ft. long. The basement contains a shop for the repair of automobiles, ample storage room for heavy machinery and parts and very complete lavatories and locker rooms for the shop and office employees. On the ground floor are the superintendents' and engineers' offices and a well equipped machine shop, forge shop and carpenter shop. On the second floor are several large rooms which are now unoccupied but which will later be used for the service of the distribution department. On this floor there is also an instrument room for the storage and care of all sorts of instruments used about the works, library and museum, main chemical laboratory, photographic dark room, photometrical laboratory, coal grinding and sample room, mechanical drafting room and construction engineers' offices.

All parts of the works are connected with the administration offices by means of an intercommunicating Select-O-Phone system.

Coal Handling—A receiving hopper was constructed on the coal bridge to work in connection with a 36-in. belt feeder conveyor. Coal dropped into this conveyor is delivered to conveyors running alongside the coal pile. There are two of these conveyors, serving nearly entire length of the coal pile, some 460 ft., the transfer station being located near the middle of the coal storage space. (Fig. 20.) These 30-in. belt conveyors carry traveling chutes, which take the coal from the feeder conveyor on the bridge. The longitudinal belts deliver to a 30-in. belt conveyor, which takes the coal from the transfer tower to the top of the coal mixing and crushing house. The conveying machinery for coal and coke was furnished by the Robins Conveying Belt Co.

The mixing and crushing building is of reinforced concrete construction with red brick panels and contains a Bradford breaker, two mixing bins, each of 100 net tons coal capacity, a refuse bin of 50 tons coal capacity,

a coal mixer and a hammer mill with the necessary electric motors and accessories for the operation of the coal machinery. The outside of the bin walls are faced with common red brick. Steel sash window frames and steel doors are provided. The coal bins are lined with reinforced glass.

The coal coming up from the transfer station is delivered to a 12-ft. x 14-ft. Bradford breaker, where the

FIG. 21. COAL BIN, OVENS AND CONVEYORS. COKE WHARF IN FOREGROUND

coal is broken to approximately $1\frac{1}{2}$ -in. size, dropping into either of the two bins. One bin is used for high volatile and one bin for low volatile coal. The coal drops from the bins through two chutes onto two coal mixing belts, where the coal is mixed, passing thence into a hammer mill or crusher with a capacity of 100 net tons per hour. This hammer mill may be by-passed, if it is not desired to pulverize the coal. The crusher and Bradford breaker were furnished by the Pennsylvania Crusher Co.

FIG. 22. SECTION THROUGH REGENERATORS AND OVEN

From the hammer mill or the by-pass, the coal drops onto a 24-in. belt conveyor, which delivers the coal to a transfer tower, thence onto another 24-in. belt conveyor to the top of the coal storage bin.

The coal storage bin is built of reinforced concrete and has a capacity of 750 net tons of crushed coal. It has steel sash window frames with double strength glass

and steel doors. The hoppers in the bin are lined with glass, and in the bottom of the bin are twelve hoppers arranged in three rows of four, each hopper being provided with a cast iron duplex gate for charging coal into the larry car. The bin is divided into two parts by a partition, so that two kinds of coal may be in storage at the same time, such as straight high volatile or high and low volatile mixture of any desired proportion. The panels on the building are filled with common red brick. A stairway is provided for access to the various parts of the building. (Fig. 21.)

When using a mixture of high and low volatile coal for making foundry coke or hard grades of domestic coke, the hammer mill or crusher is used and the coal is delivered to the coal bin pulverized so that from 80 to 85 per cent will pass a $\frac{1}{8}$ -in. mesh screen.

When using the straight high volatile coal, it is sometimes desirable to have much coarser coal, and the hammer mill is then by-passed. The capacity of the coal handling equipment is such that 700 tons, or a full day's run, of coal may be put through the plant and into the storage bins in ten hours. It is apparent that should the capacity of the plant be doubled at any future time, the coal handling equipment is sufficient to care for this increase.

Oven Battery—There are forty Koppers patented, cross-regenerative, combination, by-product coke ovens built in one battery, resting on a reinforced concrete pad, with reinforced pinion walls at each end. The ovens have a capacity of 11.4 net tons each and are 37 ft. long from face to face of doors, 9 ft. 10 in. high, $15\frac{1}{2}$ in. wide at the narrow end and 18 $\frac{1}{2}$ in. wide at the wide end. The ovens are 3 ft. 6 $\frac{1}{2}$ in. from center to center. All oven brick work exposed to high temperature is silica, the secondary portions being firebrick. Common brick is used to face the regenerators and as fill above the ovens, and the tops of the ovens are covered with paving brick.

The ovens are designed to be operated either as

FIG. 23. SECTION THROUGH OVEN HEATING FLUES

coke ovens, using part of the run of oven gas in the heating flues, or as gas ovens, using producer gas generated in an independent producer plant from coal or coke, and are designed for a 15-hr. coking time. Under each oven is a double regenerator, the walls between the double regenerators being built under the vertical heating flues and being very heavy and tight. Length-

wise through the center of the regenerator runs a light division wall. There are two lines of ports entering each flue chamber, one from each of the adjoining regenerators.

One double regenerator is entirely given over to the preheating of the air for combustion, the air from one side of the central division wall going to one set of flues and that from the other side to the next set of flues. The next adjacent double regenerator preheats

FIG. 24. CROSS-SECTION THROUGH PRODUCER MAIN

the producer gas and distributes it in a similar manner, the gas from one side of the central division wall going to one side of the oven and from the other half going to the other side. Thus, any leakage through the narrow division wall is of no importance, as air and gas are separated by the heavy walls under the flues. (Fig. 22.)

When using run of oven gas, the divided regenerators are used for air only. The oven is supplied through a fuel gas main feeding risers which serve the gas ducts just under the flues. This duct is divided into two parts, each serving approximately one-half the oven flues from opposite sides of the battery. At the base of each flue is a removable nozzle, through which the burning gas issues. (Fig. 23.) Combustion is regulated by means of a system of sliding bricks acting as dampers on the vertical flues as they lead into a horizontal flue. Each flue may be regulated independently. Also dampers are provided to regulate the draft in each regenerator outlet. The gas burns in one-half of the flues at a time at one side of the battery, the products of combustion rising to the horizontal flue, passing to the other half of the battery, down through the vertical flue to the regenerators, to the main flue, to the stack. Thus, the regenerators are reheated by the products of combustion on alternate sides of the battery.

The direction of the flow of the oven or producer gas is reversed automatically through the system of burners, flues and regenerators every thirty minutes. Thus, the regenerators return to the flues a large amount of heat which would otherwise be wasted.

The nozzle through which run of oven gas burns is located midway between two rectangular ports, each serving one-half of a generator. When using oven gas, it is not advisable to supply air for combustion to each nozzle from both sides; so it is considered good practice

to close with a brick one of these openings, allowing the air from only one opening to mingle with the gas for combustion. The next adjacent gas nozzle is served with air from the opposite side; so that the placing of the bricks closing off the air ports from the regenerators is in a sort of staggered formation. On the other hand, when the producer gas is used, the gas nozzles play no part and are closed and the bricks covering the alternate regenerator ports are removed, and in any given heating flue, one line of ports feeds gas from one-half of a double regenerator and the other line of ports feeds air from the regenerators.

Draft for the ovens is provided by a red radial brick stack 7 ft. 6 in. inside diameter and 200 ft. high. There is a main stack damper, a regulating damper for each flue, serving the two sides of the battery, and a system of reversing valves and dampers. The reversing is done automatically. A time clock, which may be adjusted for any given reversing period, actuates contact devices, which set in motion electric motors, which, in turn, operate the various apparatus concerned with reversal.

When run of oven gas is being used to heat the battery, the reversing machine operates the gas cocks on the run of oven gas lines, but when producer gas is being used, the cocks on the run of oven gas line remain closed all the time, and the reversing mechanism operates the valves on the producer gas lines, handles the dampers on the flues, opening one and closing the other for reversing the flow of products from one side of the battery to the other side, and also, at the proper time, opens the wind boxes which supply the air to the generators. (Fig. 24.)

The oven doors on the pusher side have a secondary leveling door at the top. All doors consist of a cast iron frame lined with firebrick. These doors on the coke side are handled by a Koppers door lifting machine operated by electric motors.

For pushing the coke out of the ovens, a combined pusher, leveler and door lifting machine is employed, carrying a ram which pushes the coke from the oven, a motor rope driven leveling bar to level the coal in the

FIG. 25. COKE PUSHER AND LEVELER

ovens, a door ram to remove the oven doors and a carbon scraper. (Fig. 25.) On the coke side, there is a door machine, which handles the doors, and a coke guide, which is constructed of steel and which directs the movement of the coke across the coke bench into the quenching car. The coke is received in a coke quenching car with a capacity for one oven, which has air operated cylinders for opening the doors. (Fig. 26.) The bot-

tom of the car is lined with cast iron plates and the ends of the car with steel plate. This car is handled by a 15-ton electric locomotive. After the coke is received in the car, it is taken to the quenching station.

For charging the coal into the ovens, there is provided a coal charging larry, electrically driven, which has four coal hoppers made of 1-in. steel plate. (Fig. 27.) During the charging of the oven, a sort of valve comes down on the coal hole frame, which largely prevents smoke from escaping at this point. The smoke

FIG. 26. MUD CAR, COKE GUIDE AND COKE QUENCHER

flue extends the entire length of the coke side of the battery and connects with the battery stack. A telescopic pipe mounted on a carriage can be used to connect the smoke offtakes of any oven to any smoke flue through a mushroom valve acting in connection with telescopic pipe mounted on a carriage. Most of the smoke generated during charging can be drawn up through this telescopic pipe into the smoke flue and thence to the stack. The operation of removing the doors, pushing the coke, replacing the doors, charging the coal, leveling same and replacing coal hole lids is accomplished very smoothly and quickly with a minimum of disturbance. Three clay carriers are provided—two on the coke side and one on the pusher side—and as fast as the oven doors are replaced they are luted with clay, which is prepared in a clay mixer located under the coal bin.

The run of oven gas, after passing through a wet meter, is brought back to the battery through a 12-in. fuel gas main, a short pipe running from this main to each gas burner, the gas burners being provided with shut-off cocks, carbon caps, etc.

From each oven a short 13-in. cast iron ascension pipe carries the gas from the ovens to the gas collecting main. In the upper section is a butterfly valve and a cleaning door, the ascension pipes entering the collecting main at one side. The collecting main serves the entire battery and is circular in cross section, 54-in. in diameter, sloping from each end to the center, at which point the offtake main connects. This main is provided with the necessary cleaning holes and is built of 3-in. steel plates with a walkway on the top. Sliding plate dampers are provided each side of the offtake main, so that one-half of the battery may be cut off at a time. The offtake main is 30 in. in diameter and is built up of riveted pipe. This main runs over to the producer house wall, supported on a steel bridge.

The gas then passes into a down-comer, which is built of two vertical cylinders, one telescoping the other, the outer portion being 4 ft. 4 in. in diameter and 10 ft. long, with a conical bottom, dipping into a seal tank. The inner portion is 30 in. in diameter and 8 ft. 9 in. long. The condensates from the gas and flushing liquor pass down through the down-comer, into the pitch trap and seal tank. The gas passes from the inner pipe to the opening at the top of the larger portion, thence through 30-in. riveted pipe from the top of the down-comer to the ground, then underground to the by-product house. A circulating tank 15 ft. diameter and 9 ft. high built of steel plate with a partition is located at the yard level, this tank being used for supplying tar and liquor for flushing purposes.

Coke Handling—The coke, which is received in the quenching car, is carried to the quenching station, which consists of a quenching and settling basin and a quenching tank. The hood is 20 ft. wide and 50 ft. long and has a total height of 60 ft., being built of brick, open at one end only, so that the quenching car can enter. The water tank is of steel and has a capacity of 7500 gal., being supported overhead on a steel framework about 60 ft. from the ground. A stray pipe is located under the quenching hood. Two motor driven pumps are provided for handling the quenching water, which is recirculated from the sump through the settling basin, etc. The sprays have quick-opening valves and discharge the contents of the tank in 35 to 60 seconds. The coke car, after having received the charge of quenching water, is drawn out from the hood and allowed to stand for a few minutes for draining, the drained water running back into the sump. A small amount of makeup water is required each day to take the place of steam driven off. The quenching hood being some 60 ft. in height throws the rush of steam and vapor high above the yard level. After standing the necessary time, the coke is drawn along the coke road to the

FIG. 27. LARRY CAR AND TOP OF OVENS

coke wharf, which is at the opposite end of the battery from the quenching station. This coke wharf is 48 ft. long and is built of reinforced concrete with cast iron plates and is provided with finger gates and feeders. The coke is fed onto a 36-in. belt conveyor, with a capacity of 10 tons per hour, which runs alongside the coke wharf, then rises to the foundry screening station. The foundry screening station is built of reinforced concrete with red brick panels. The run of oven coke is delivered by the belt conveyor to a rotary grizzly, from

which a 36-in. shuttle belt conveyor delivers the foundry coke to open top coke cars on a railroad track alongside. The smaller sizes of coke dropping through the grizzly fall onto a belt conveyor, which ascends to a transfer station, then transferring to another ascending belt rises to the elevation of the telfer lines, passing along under the telfer lines.

Under the telfer lines is a system of rotary grizzlies, which may be operated in several ways. The egg, stove, nut, pea and breeze coke come first to a rotary grizzly, which takes out the egg and drops it into a bay underneath the telfer lines, whence it can be rehandled. The coke then passes to a second set of grizzlies, which take out the stove size, which likewise falls into its proper bay. The nut, pea and breeze then go on a belt to a pit or bin adjacent to the screen houses, where they are, in turn, deposited. From this pit either one of two telfers can pick them up and send them to either of two shaker screen houses, where they are separated into their respective sizes.

Likewise, should the storage piles be full, or if, for any other reason, it is undesirable to separate the egg and stove on the rotary grizzlies, these can be by-passed and all sizes go to the pit, whence they are sent through the shaker screen houses.

FLEXIBILITY OF THE SYSTEM

This makes a very flexible arrangement, so that if the shaker screen houses are down for any reason, the production of egg or stove size is not stopped, as the rotary grizzlies can take care of this; also should the egg and stove piles be well filled under the rotary grizzlies, the shaker screen houses can be called upon to make all five sizes of coke.

In addition to the above arrangement, when foundry coke is not being made or if it is desired to send run of oven coke direct to railroad cars, plates may be put on the grizzly; so that all the coke will drop onto the shuttle belt which goes to the cars. If it is desired to make all domestic coke and no foundry, the foundry grizzly is run, but the large sizes which go over this grizzly and drop onto the shuttle belt are carried to a coke crusher. By reversing the direction of this shuttle belt, this coke crusher breaks the large sizes into domestic sizes, which, dropping through the crusher, are caught on the same belt which is handling those sizes of coke which fell through the foundry grizzly, and thus the whole output of coke in domestic sizes is carried up to the rotary grizzlies under the telfer lines, where the egg and stove are prepared, and also, by the shaker houses, the nut, pea and breeze sizes of coke.

It will be noted that great care has been taken in arranging the coke handling system to avoid tie-ups due to any particular set of conditions, and it is believed that this arrangement will take care of the entire output of coke from the ovens without further additions for some time to come.

The run of oven coke carried by the belt to the foundry screen house is automatically weighed by a Merrick weightometer, so that an accurate weight is obtained on the yield of coke from the coal daily.

After the coke is passed through the shaking screen stations, it drops into bins, from which it can be chuted directly into trucks or wagons or handled into cars, trucks or wagons by the telfers.

A large amount of coke is also handled in paper

bags and canvas bags. Small size coke for domestic use is delivered in canvas bags, which are filled in the screening station and placed on a roller conveyor, which automatically transfers them to a wagon loading house, which is 90 ft. long and 29 ft. wide and which will provide ample storage for bags and from which as many as sixteen teams may be loaded at one time. In all as many as forty teams and trucks can be loaded with bag and bulk coke in different parts of the yard, which is considered ample for the domestic trade that is anticipated.

For loading foundry coke, one shuttle belt loader combined with a box car loader will take care of one car to be loaded as the coke is made. Locomotive cranes can also load from storage piles. On the north side of the producer house is a set of track hoppers served by the telfer lines, from which coke may be loaded into four cars at a time for railroad shipment. In addition to this, it is planned to put bins for loading at least two cars under the telfer lines in other parts of the yard, so that in all, including foundry coke and domestic sizes, as many as eight railway cars of 30 to 40 tons capacity can be loaded at any given time.

Condensing and Deammoniating Plant—The condensing plant built by the Bartlett Hayward Co. for handling the 3,000,000 cu.ft. of retort gas consisted of water tube condensers, P. & A. tar extractors and rotary scrubbers. This equipment has been utilized exactly as it stood with the exception of a few minor changes in the movement of scrubber water, liquor, etc. A new exhauster was added, making three in all. Two are used, with the third as a spare. There was ample room in the building for the addition of this third exhauster.

It became necessary to provide gas treating apparatus for 4,000,000 cu.ft. of gas to take care of the total of 7,000,000 which it was contemplated the new coke ovens would produce. Various systems were considered. Had the conditions in the industrial world been normal and the prices such as to make the investment reasonable, it is probable that a complete new by-product plant would have been built, probably of the Koppers system, but funds were not available for such a development at the time and it was felt that the extension of this part of the plant must be made as economically as possible. The Steere Engineering Co. of Detroit had in the past few years developed a system of handling gas for condensing and deammoniating, which had previously attracted the writer's attention and which appeared to be a possible solution of the present problem. The engineers of the Steere Engineering Co. were invited to study the local situation and prepare plans for condensing and deammoniating equipment, which were duly completed and submitted and, with some slight changes, accepted by the company. The gas coming from the ovens in an underground main divides between the old primary condensers and the new Doherty washer cooler as designed by the Steere Engineering Co.

This washer cooler consists of a steel plate shell 5 ft. in diameter and 29 ft. high, packed with wooden grids after the manner of the tar scrubber. Over these grids liquor is circulated by means of electrically driven centrifugal pumps. The gas then passes through the exhausters and tar extractors and again divides, the proper proportion going to a secondary washer cooler, where the temperature is brought down as low as 60

deg. F. if desired. The wash liquor which is pumped over the grids in the washer cooler goes from the base of the coolers through a series of cooling coils, which are set up in a convenient location adjoining the building. Cold water runs down over these cooling coils from suitable troughs and the cooling of the recirculating wash liquor is thereby quickly and economically effected by means of direct contact between the cold incoming wash liquor and the gas. Very complete transfer of heat is secured and the heat potential is much less than with multitubular water condensers.

SATISFACTORY WORK BY WASHER COOLERS

The operation of these washer coolers is highly satisfactory. The condensed liquor and tar from them forms a surplus, which overflows from the base of the scrubbers through a seal to the main tar liquor separators for the ammonia storage wells. After leaving the secondary washer coolers, the streams of gas again come together and pass through the old Feld washer, thence through the two rotary scrubbers and finally through the intensive scrubber supplied by the Steere Engineering Co. This intensive scrubber is 15 ft. long, 6 ft. 6 in. wide and 22 ft. high and contains four compartments filled with wooden grids, over which the wash liquor is circulated by means of four motor driven centrifugal pumps. Fresh water is admitted to the last compartment and the wash liquor is recirculated in this compartment, then passing progressively through each of the other three compartments, finally discharging to a tank in the condenser house, underneath one of the rotary scrubbers. From this tank the liquor is picked up and recirculated through the two rotary scrubbers, the effluent discharging into a second tank located underneath the other rotary scrubber. From this tank liquor is picked up by a steam pump and recirculated through the Feld washer, the final effluent discharging into the main ammonia storage well.

This system of recirculation of the ammonia liquor results in scrubbing out considerable portions of hydrogen sulphide and carbon dioxide in combination with the ammonia gas and is remarkably efficient in recovery of ammonia. Tests show that when using $1\frac{1}{2}$ gal. of water to a thousand cu.ft. of gas, not more than one grain of ammonia per 100 cu.ft. of gas is lost at the outlet of the intensive scrubber. The liquor through the entire plant, including suction main, condensers, washers and scrubbers, may be made of any desired strength between 1 and 2 per cent by varying the amount of fresh water entering the intensive scrubber. Although the washer cooler and the intensive scrubber appear very small in size for the work which they have been called upon to do, careful tests show that they are amply large and since starting up have worked with great satisfaction.

Molybdenum Steel in the U. S.

During the past 18 months about 50,000 tons of molybdenum steel has been made in this country with very encouraging results, and it is now understood that some of the leading alloy steel makers believe that steel containing a relatively small quantity of molybdenum is superior to any other known material for high-grade aeroplane parts, such as crank shafts. The other alloying metals making up the steels are variously reported as nickel, vanadium and chromium.

Cementing Jamb Joints

IN THE operation of the 40 Koppers coke ovens recently installed by the Providence Gas Co., the method used to seal effectively the joint between fire clay and silica brick construction, where the tenth' in. per ft. difference in expansion ordinarily would disrupt the joint and cause leakage, may have wide applicability. The size of each coking section is 40 ft. by 17 in. and the time required for coking approximately 15 hours.

Where brick work was subjected to highest temperature the finest grade silica brick was used. For face, top and checker brick, as well as oven floor, fire clay brick was employed. At the junction point between the silica and fire clay brick the difference in coefficient of expansion of the brick requires the use of cement which will seal the slip joint firmly

and prevent leakage. Diagram of this joint is shown in Fig. 1.

After trying several mixtures it was found that the best results were obtained by the use of hytempite, a high temperature refractory cement furnished by the Quigley Furnace Specialties Co., Inc., of New York.

A spraying device as shown in Fig. 2, being a modi-

FIG. 1. SLIP JOINT JUNCTION

FIG. 2. APPARATUS FOR SPRAYING DILUTE HYTEMPITE INTO THE JAMB CRACK

fied type of paint sprayer made by the Spray Engineering Co. of Boston, is employed using hytempite as follows:

Dissolve hytempite in warm water in the proportion of 1 pail of hytempite to approximately $\frac{1}{2}$ pail of warm water. Stir and mix well. Pass through $\frac{1}{8}$ -in. wire mesh into the container used for blowing solution into the jamb crack.

¹Fire clay brick, 0.075 in. per ft.; silica brick, 0.175 in. per ft. at 2200 deg. F. = Δ 0.1 in. ft.

FIG. 3. DETAIL SHOWING SPRAYING JOINT WITH HYTEMPITE

Clean face of jamb bricks thoroughly, also clean the rougher material from jamb crack, with the steel tool provided for that purpose. Then apply full air pressure, approximately 50 lb., through the pipe used for patching, cleaning crack thoroughly before applying the so-

FIG. 4. FINISHING OFF WITH TROWEL

lution of hytempite. Then turn air into the hytempite container, being careful not to use too much air pressure, open proper valves and apply solution to the crack by means of the pipe and hose which are provided. See Fig. 3.

After the crack has been filled with the solution, if any portion of it remains open, smooth over with neat hytempite, using long handled trowel. By using a corrugated shield as shown in Fig. 4 the operator is enabled to carry on repairs while ovens are hot.

Mining and Metallurgical Situation in Belgium in 1919

THE first official data on the situation of the Belgian industries at the beginning of 1919 have just reached this country. The latest issue of the *Annales des Mines de Belgique* received here contains a report of the investigation instituted by the Belgian Department of Industry and Labor on some mining and metallurgical industries.¹ The following is a short abstract of this report:

COAL MINING

It can be said that of all the Belgian industries this is the one which has suffered the least from wanton destruction. This is explained not by the thought that the Germans had any consideration for the Belgians and their coal industry, but by the fact that during the first four years of the war they treated the coal mines as theirs, and only the lack of time during the last few months of the war saved the Belgian mines from the fate of the mines in northern France.

The mining situation is best shown by Table I, which gives the production for 1913 to 1918 by coal districts and totals.

TABLE I—COAL PRODUCTION IN BELGIUM, METRIC TONS

Year	Mons	Centre	Charleroi	Namur	Liège	Total
1913.	4,406,550	3,454,640	8,148,020	829,900	5,998,480	22,841,590
1914.	3,578,840	2,701,550	5,764,410	534,180	4,135,070	16,714,050
1915.	3,310,200	2,573,430	5,375,690	410,660	4,007,520	14,177,500
1916.	3,705,540	3,212,860	5,223,970	497,150	4,223,350	16,862,870
1917.	3,869,680	2,785,400	4,671,240	437,870	3,155,510	14,919,700
1918.	3,281,720	2,559,610	4,493,630	374,440	3,112,530	13,821,930

In the new coal district of Campine, which was ready to start actual mining Aug. 4, 1914, and from which the Belgians reasonably expected to get the needed additional fuel, the total mining amounted to 11,640 tons in 1917 and 65,670 tons in 1918.

COKE

Of the Belgian coke ovens it is stated: Some have been in operation without the needed repairs, some have been totally destroyed (especially those of the Cockerill plants) and the remainder have been totally dismantled, and the installations for by-product recovery carried away or destroyed.

The results of this policy are shown in Table II, which gives the production, 1913-18, by provinces and totals.

TABLE II—COKE PRODUCTION IN BELGIUM, METRIC TONS

Year	Hainaut	Liège	Other Provinces	Total
1913.	2,220,180	877,130	445,690	3,523,000
1914.	1,406,460	595,210	?	2,001,670
1915.	424,460	90,140	?	514,600
1916.	667,530	124,820	?	792,350
1917.	648,210	27,830	?	676,040
1918.	509,150	13,060	?	522,210

IRON AND STEEL INDUSTRY

This industry has suffered more than any other. Were it not for the figures given in Table IV, it would be difficult to realize the fate which has befallen the industry which was the pride of the Belgians. The list of examples of destruction includes every district in every province, and the once well-known skilled Belgian metallurgist is forced to labor—not only for the present, but for many years to come—with pick and shovel, in order to clear away the ruins and rebuild the plants.

¹La situation des Industries en Belgique, en février 1919, après les dévastations allemandes. *Annales des Mines de Belgique*, 2ème livraison, Tome XX, 1919, pp. 695-711.

TABLE III—IRON AND STEEL PRODUCTION IN BELGIUM, METRIC TONS

Year	Hainaut	Liège	Namur	Other Provinces	Total
1913	1,189,650	896,360	31,030	107,020	2,224,060
1914	641,560	519,860	14,870	62,490	1,247,410
1915	76,590	85,560	2,200	164,370	208,720
1916	130,945	90,260		2,110	200,821
1917					
1918					

BRIQUETTES

The Belgian railways use briquetted fuel exclusively, which accounts for the fact that the briquetting plants were in most cases unharmed.

Table IV gives the production for 1913 to 1917 by provinces and totals.

TABLE IV—BRIQUETTE PRODUCTION IN BELGIUM, METRIC TONS

Year	Hainaut	Namur	Liège	Other Provinces	Total
1913	1,864,200	171,010	453,350	120,000	2,608,640
1914	1,371,480	128,730	299,490	?	1,799,700
1915	968,470	135,220	386,410	?	1,409,100
1916	1,300,850	166,710	468,260	?	1,935,820
1917	707,690	70,130	204,110	?	981,930

ZINC AND LEAD

The place occupied by Belgium in these industries about five years ago is well known, but today Table V shows what premeditated destruction can accomplish.

TABLE V—ZINC AND LEAD PRODUCTION IN BELGIUM, METRIC TONS

Year	Zinc		Lead
	Ingot	Rolled	
1913	204,220	51,490	103,480
1914	145,925	30,780	70,980
1915	51,660	21,350	16,770
1916	22,930	8,045	15,560
1917	10,290	1,675	22,745
1918			

The report contains, among other examples of destruction, the case of the plants of the Dumont Frères Co. of Sclaigneaux (near Liège). These plants, especially the lead plants, which had been thoroughly modernized shortly before the war, have been completely dismantled, and all the machinery and even the roof trusses have been shipped away.

The grim comparative statement is made that the metallurgical plants of Hoboken (near Antwerp) and Overpelt, which are owned by German capital, are now in just as good working condition as ever.

Synopsis of Recent Chemical and Metallurgical Literature

Present American Acid Bessemer Process—RICHARD S. McCAFFERY, professor of metallurgy, University of Wisconsin, published in the January issue of the *Wisconsin Engineer* a paper presenting his conclusions on the reversibility of manganese oxidation. He starts from a consideration of the data given in Table I.

With a gradually increasing heat, manganese carbide burns to MnO and CO₂. However, if hot-pig or high-silicon iron is blown, the temperature runs up so rapidly that MnC₂ is retained in the bath to the end since under these conditions this compound will produce CO rather than CO₂. Any manganese carbide retained acts as a powerful reducer, returning silicon to the bath, and re-

ducing FeO to Fe, forming a more basic, infusible slag containing ferrites, which is largely responsible for the excessive spitting of a hot blow. Under these circumstances there appears to be residual manganese in the steel, not on account of the reversibility of the reaction $2\text{Mn} + \text{O} \rightleftharpoons 2\text{MnO}$, but on account of the fact that the carbide is residual. In this case silicon is always residual as well. (Of course when it is said that

TABLE I

Substance	Formula	Oxidation Products	Calories per Gram Atom of Metal
Silicide of iron	FeSi	Fe ₂ O ₃ , SiO ₂	245
Carbide of manganese	MnC	MnO, CO	171
Silicide of manganese	MnSi	MnO, SiO ₂	135
Carbide of iron	Fe ₃ C	Fe ₂ O ₃ , CO	98
Carbide of iron	Fe ₂ C	Fe ₂ O ₃ , CO	75
Carbide of manganese	MnC	MnO, CO	35

iron silicide burns first, it means that a number of reactions are taking place at the same time, but that this reaction predominates.)

Since it was desired to find some remedy for the excessive spitting, this could evidently be reduced by close temperature regulation. This in turn could be done by three different methods: first, by charging cold scrap—which was not always available; second, by blowing steam through the tuyeres—which was costly, and third, by increasing the number of tuyeres and reducing the air pressure. Quite often the high air pressure drove oxygen clear through the metallic bath during the carbon blow, and this unconsumed oxygen burned CO to CO₂ within the shell, thus increasing the temperature of the bath and the air cost. Therefore, at the author's suggestion the number of tuyeres was increased from 23 to 35, and the blast pressure dropped from 28 to 22 lb. When running on successive heats from the same mixture the modified converter reduced the blowing time from 14 min. to 10 min. 20 sec., saved 40 per cent of blowing engine power, and entirely reduced the spitting.

Book Reviews

OPPORTUNITIES IN CHEMISTRY. By *Ellwood Hendrick*, Consulting Editor, *CHEMICAL & METALLURGICAL ENGINEERING*. x + 102 pages. New York: Harper & Bros.

This book is one of a series intended to aid the returned soldier in vocational rehabilitation by pointing out the possibilities afforded by different industries. While written primarily for this purpose, this little book is admirably adapted to serve as an introduction to the author's larger work, *Everyman's Chemistry*, and thus to stimulate popular interest in the study of chemistry as an important adjunct to all branches of business activity. The style is intimate and conversational, so that the reader follows with interest expositions of processes and theories which, treated in text-book fashion, would prove unattractive to the general reader.

Beginning with a short outline of certain fundamental concepts, such as elements, atoms, molecules and electrons, the reader's attention is directed in turn to the great cycle of nature, by virtue of which the sun's energy is locked up in growing vegetation; the activities of the soil—invisible to the naked eye, yet responsible for the growth of crops; the mysteries of catalysis; the chemist's tiny allies—the yeasts, molds and bacteria; the manufacture of soap and its application in the laundry business; the earth as raw material and, finally, iron and steel.

It is doubtful if anyone can read the book without feel-

ing an increased interest in chemistry, not only as a science in itself, but as an aid to the better understanding of one's own business and, to quote the author in conclusion, "After all, that is the most important part of a man's working life—that his job shall be interesting to him."

ALAN G. WIKOFF.

Personal

MR. WARREN F. BLEECKER of Boulder, Colo., was in New York recently.

MR. R. V. COOK, recently research engineer with the Koppers Co. of Pittsburgh, has joined the sales-engineering staff of the Brecht Co., St. Louis, Mo. He will have charge of the sales and erection of the new Brecht standard oil-hydrogenating plant which has just been introduced.

MR. WILLIAM E. COREY, chairman of the Midvale Steel & Ordnance Co., has been elected a director of the Sinclair Consolidated Oil Corp.

DR. F. G. COTTRELL, chief metallurgist in the U. S. Bureau of Mines, has been named assistant director in charge of investigative and scientific work. Other changes in the Bureau are the appointment of the former chief clerk, MR. F. J. BAILEY, as assistant to Director Manning in charge of executive work, and MR. H. W. MEYER, chief clerk of the War Minerals Relief Commission, to be chief clerk of the Bureau, succeeding Mr. Bailey.

MR. ALGERNON DEL MAR, milling and flotation engineer, has opened an office at 1424 Alpha St., Los Angeles, Cal., and will conduct a business in the design and operation of milling plants.

MR. R. C. GEMMELL, general manager of the Utah Copper Co., will become assistant managing director of that company and other interests of D. C. Jackling, effective Aug. 1. Besides the Utah Copper Co., Mr. Gemmell will assist in the direction of the Nevada Consolidated Copper Co., Ray Consolidated Copper Co. and Chino Copper Co. MR. LOUIS S. CATES, at present general manager of the Ray Consolidated Copper Co., will become assistant general manager of the Utah Copper Co. on Aug. 1, with offices in Salt Lake City.

MR. C. W. HARE, director of sales, War Department, sailed for Europe July 21 with a party of 22 to ascertain European conditions for the disposal of surplus property now held by the War Department in the United States.

PROF. SAMUEL HOYT has resigned as assistant professor of metallography, University of Minnesota, Minneapolis, to accept a position as metalligraphist for the National Electric Lamp Association, Nela Park, Cleveland.

MR. D. S. McAFEE, engineer of the Dorr Co., has returned from Chile.

MR. GEORGE MESTA, president of the Mesta Machine Co., Pittsburgh, has sailed for Europe on a pleasure and business trip combined, to be gone until November.

MR. LEWIS A. PARSONS has resigned from the International Nickel Co. of Canada and accepted a position on the *Mining and Scientific Press* as associate editor.

MR. WILLIAM C. POTTER, of Guggenheim Bros., is a member of the board of directors of the Mexican International Corporation, recently organized to finance new enterprises in Mexico.

MR. THOMAS T. READ, formerly associate editor of the *Mining and Scientific Press*, has joined the staff of the Bureau of Mines and will investigate the work of the Bureau in relation to public welfare.

MAJOR F. H. SCHOENFESS, lately discharged as metallurgical expert from the United States Ordnance Department, where he had charge of the specifications for the heat-treatment of all parts of various types of guns, has become associated with John H. Brewster, 30 East 47th St., New York City, American representative of the Fagersta Steel Co., Fagersta, Sweden, maker of carbon and alloy steels.

MR. W. H. STAYER, mining and metallurgical engineer, of New York City, is on a business trip to Denver and other points in the West.

DR. SAMUEL A. TUCKER, formerly professor of electrochemistry at Columbia University, who served as Major in the Chemical Warfare Service, is now chief chemist for the Chemical Foundation, Inc.

MR. C. H. VOM BAUR has resigned as vice-president of the T. W. Price Engineering Co., Woolworth Bldg., New York, and will soon establish an office for the sale of the vom Baur electric furnace.

MR. M. W. VON BERNEWITZ has resigned as assistant editor of the *Mining and Scientific Press* and has come to New York to collaborate with Walter H. Weed on the Mines Handbook.

MR. C. M. WELD, consulting mining engineer, has returned from war work in Washington, and resumed practice with offices at 66 Broadway, New York.

MAJOR CLARENCE J. WEST, recently in charge of the editorial department, research division, Chemical Warfare Service, has joined the staff of Arthur D. Little, Inc., Cambridge, Mass., as director of the information department. While with the Chemical Warfare Service he prepared about fifty monographs on different phases of chemical warfare, dealing particularly with war gases, smokes, incendiaries, absorbers, etc. In his new position Major West will extend the library facilities of the organization and develop a special information service on technical and scientific subjects.

Obituary

MR. CLARENCE W. HATHAWAY, metallurgist for the last eight years for the Granite City Steel Works Branch of the National Enameling & Stamping Co., met his death by drowning while swimming with a party of friends in the Mississippi River on July 19 at Granite City, Illinois. He was born in Columbus, Ohio, in 1886, and was educated in the schools of that place and at the Ohio State University, Columbus, Ohio. He had previously been employed with the U. S. Steel Corporation at Gary, Indiana, before accepting his last position. He leaves a wife, father and mother, one brother and four sisters. Mr. Hathaway was a member of the Masons and Elks; and of the American Chemical Society, Metallurgical Society of America, and the American Ceramic Society.

Current Market Reports

Tuesday, July 29.—The general rise in prices noted in the last report has continued during the past fortnight, due to an increase in both the export and the domestic demand.

Lead:—The price has advanced to 5.85-6.00c. for New York delivery and 5.50-5.75c. for East St. Louis shipment.

Tin:—London prices have advanced almost daily, Straits, spot, being now quoted at £272 per ton. The general New York quotations on Straits, spot, is 71c.; electrolytic, 99 per cent, 66½-68c. Tin ore is arriving in ever-increasing amounts. During the week of July 14-21, 1850 tons were received from Bolivia.

Zinc:—Spot spelter continues to advance. East St. Louis, 7.70-7.80c.; New York, 8.25c.

Aluminum.—The market is reported quiet and 98-99 per cent ingots are now quoted at 33c. lb. Scrap continues to advance: Cast, 23-24c.; sheet, 24-25c.; clippings, 26-27c.

Antimony.—It is reported that considerable export trade to Europe has developed and the market has therefore assumed a much firmer aspect. The present quotation for spot regulus ranges from 91-94c.

Copper.—The rapid rise in the copper market during the past few weeks has brought the price for spot delivery to 23½c. Buyers who have bought copper for a rise now see enough profit to let go of some of their holdings, and this has stopped the further upward movement for the time being. Quotations are: Spot and July, 23½-23¾c. August, 23½-23¾c.; September, 24c.

The Iron and Steel Market

When the seasonal correction is applied to the reading given by the order books of the steel mills a very favorable showing is made of the strength of the market. July and August are normally very dull months in the steel trade, but this year the volume of domestic business is showing for July a slight gain over June. In export business this is not the case, there being somewhat less activity, but that is undoubtedly due to causes other than the season, and beyond the control of the steel trade.

The trends of steel mill activity are well shown by proportioning the ingot production, reported monthly, to an estimated capacity of 49,000,000 gross tons per annum. This gives the following percentages of activity, as averages for the months: January, 87 per cent; February, 85; March, 77; April, 65; May, 54; June, 67. The low point fell in May, which, with an average of 54 per cent for the month, must have had a low point at about the middle of the month of approximately 50 per cent. June, with a sharp increase in total production, must have had a rate of about 70 per cent at the close of the month. The rate has probably not increased materially since the first of July. The July average, when reported, will probably lie between 70 and 75 per cent.

STEEL TRADE CONDITIONS BECOMING MORE NORMAL

Conditions affecting the steel trade have altered toward the normal by a sufficient amount to justify a long-range scrutiny to determine when and how full activity in the industry may be developed. Early in the year the tonnage turned out by the mills constituted no index to the future, as the industry seemed to be running on momentum to an extent. Just why it operated as well as it did cannot readily be explained, nor if the explanation were available would it be of particular value as a foreshadowing of what should be expected for the future. The fact that the low point in steel production fell six months after hostilities were terminated by the signing of the armistice indicates very plainly that what occurred in the fore part of the intervening six months could not be indicative of what would occur in the trade later.

Assuming that the steel industry has operated in July at a rate of producing 35,000,000 tons of ingots a year, which is 70 per cent of an estimated capacity of 49,000,000 tons, this 35,000,000 tons is equal to what may be estimated as the entire capacity in 1914, there having been a 40 per

cent increase in steel producing capacity, though hardly in steel finishing capacity, during the war. In both 1912 and 1913, easily the best pre-war years from a tonnage standpoint, ingot production was about 30,280,000 tons. Thus production in July was 16 per cent in excess of the best sustained average before the war. Exports of steel and steel manufactures, reduced to an ingot basis, represented about 3,000,000 tons a year in 1912 and 1913, and represent about 5,500,000 tons at present, and thus one has it that production of ingots for purely domestic consumption is now at about two and a quarter million tons a year, or about 8 per cent, more than in 1912-13.

INDIVIDUAL CASES OF STEEL CONSUMPTION

With this general guide as to total tonnages, one may readily compare individual cases of consumption. The automobile industry is consuming much more steel than ever before, and so is the petroleum industry, for the lap weld departments of the pipe mills are filled with orders for practically the remainder of the year, although their orders outside the petroleum industry have been distinctly light. Dwelling house construction is, or soon will be, fully up to a normal rate. Construction work involving large projects, skyscraper hotel and office buildings, bridges, power plants and factories is far below normal, although steadily increasing. Shipbuilding is at the rate of about 500,000 tons deadweight a month, and that may prove to be the normal rate for several years, but lately shipbuilding has been largely with steel accumulated during the war as a factor of safety, so that later on the shipyards will be calling for more steel from the mills. Railroad buying is completely absent. The normal production of railroad consumption of steel to total steel production has usually been exaggerated, some estimates having been as high as 30 or 40 per cent. A liberal estimate seems to be 20 per cent, with a 5 per cent leeway in either direction.

From this rough sketch it is readily seen that demand has opportunity to grow from its present volume by an amount easily sufficient to take up the slack between the present 70 per cent operation and a full operation, and that without any increase in export demand.

EXPORT DEMAND

It would be quite unsafe to count upon an increase in export demand, particularly as the export bookings in July ran below those of June. The purchasing power in foreign countries is limited and in Great Britain and on the Continent exchange rates are very unfavorable. The condition is one that the steel industry itself can do little to rectify, but one that the United States, or the American people, can and should entirely rectify. We have been expecting financially impoverished nations to buy goods from us because we have goods, ignoring the fact that when we have much more money than they we should also buy from them. As a matter of self-interest the steamship companies, desiring return hauls, will probably do much to encourage an import trade, and the divergence in exchange rates will also have a favorable influence.

There is little likelihood that steel prices will change much during the remainder of this year. It is now practically assured that there will be no declines in important commodities, with the possible exception of plates, where there is so great an excess of capacity. The market has successfully stood the test of there being a period of price cutting, in which the mills with the leanest order books bought their way into the market and then resumed quoting full prices. As to advances, there is less sentiment among steel mills in favor of making advances than there was a month ago. With a larger volume of business they are better satisfied with existing prices, which are those that became effective March 21, and they have come to realize that advanced prices, perhaps of doubtful benefit in themselves, would probably precipitate labor unrest and might easily lead to advanced wages. The advanced wages would be permanently fastened on the industry, while the advanced prices might yield at any time. Here and there an independent steel producer has advanced prices on one product or another, but these advances have not taken hold generally and are not especially popular.

The Chemical Market

New York, July 28, 1919.

The increasing foreign demand has stiffened and stabilized the entire line of heavy chemicals. Among those most urgently sought are *sodium bichromate* (by England and South America), and *caustic soda* (by Japan and South America). In addition to this, it is reported that a number of domestic contracts have been placed for these two products, covering the balance of the year. *Sodium bichromate* is probably the strongest item on the list, having advanced 37 per cent since last writing, present price being 11-12c. Not long ago it was selling below cost.

Caustic soda continues to mount, under the guidance of the United States Alkali Association, which has just boosted the export price from \$3.30 up to \$3.50 per cwt., f.a.s., New York. *Muriatic acid* has risen $\frac{1}{2}$ c., because of curtailed production and short stocks. As for *potassium prussiate*, there are only two tons on the market to-day, with the price 55-65c. against 40-50c. two weeks ago. It is expected that stocks will shortly be replenished, with relief to the buyers and sellers alike.

Copper sulphate (blue vitrol) reflects the present higher price of copper. However, although the price for moderate quantities is \$9.15-\$9.25 and quoted at \$9 for carloads, it is possible to obtain the latter at \$8.75 per cwt.

NAVAL STORES

Except during the Civil War, turpentine and rosins were never higher than at present. Both are selling heavily in foreign markets as well as in the domestic, with the result that spot stocks here are scarce. At this writing spirits of turpentine is quoted at \$1.27 per gal., against \$1.05 two weeks ago. During the war, Europe produced practically no naval stores, so is now buying heavily in this country. Another factor of importance in explaining high prices is the tie-up of coastwise shipping, which affects the ports of New York, Boston, Savannah, New Orleans, Galveston and Norfolk.

VEGETABLE OILS

The speculative feature, which for many weeks has characterized the vegetable-oil market, is beginning to disappear. What little oil there is, is in the hands of manufacturers and wholesalers who, under present conditions, are in no hurry to sell. It is believed in some quarters that vegetable oils have attained the apex. No advance is expected unless a heavy buyer enters the market. This opinion is substantiated by the fact that the purchase of only 660 bbl. of soya bean oil last week sent the price up a cent.

Is the present price of linseed oil too high? Well, it was never higher—even during the stress of war. Shortage of seed is the reason given, but there are dealers who admit that inflation is a still better reason. In the first week of June raw in 5-bbl. lots sold for \$1.59 per gal.; second week, \$1.83; third week, \$1.90; first week of July, \$1.90; second week \$2.15; third week, \$2.20—an increase of 38 per cent in less than two months. It would seem that linseed oil has succumbed to the speculative fever that has been ravaging the vegetable-oil market for some time.

As a result of increased domestic consumption soya bean oil has advanced in price, which now is 18c. per lb. in tank cars, f.o.b. Pacific Coast, as compared with 16 $\frac{1}{2}$ -17 $\frac{1}{4}$ c. at the last writing. It is expected to go even higher, due to lax buying in the Orient. Domestic demand is quickening.

Castor oil should advance sharply in the near future, owing to the usual fall demand by the textile mills and tanners. No castor beans are being grown in the United States this year, necessitating entire dependence on Brazil. Brazil has already shipped large quantities of seed to France.

St. Louis, July 23, 1919.

The fertilizer manufacturers, who started the original heavy demand for 60 per cent *sulphuric acid*, have kept up their demands so insistently that the price is expected to rise within the next few weeks. One local producer put a new plant in operation the first part of the month and

already is swamped by orders. The price holds steady at \$12 a ton.

The 66 per cent *sulphuric* is normal, demands being steady but not heavy, the price remaining at \$18 a ton. The demand for *oleum* also is normal and the price remains the same.

Muriatic acid is in immense demand. Producers are frankly at a loss to know where the supply is going and why orders should be so heavy. One producer believes that a shortage of tank cars is being felt, which is causing buyers to place numerous orders in the hopes of getting through the amount of muriatic they desire. Prices hold steady at \$22 a ton for 18 per cent.

Sodium bisulphate (niter cake) is reported oversold. Orders are being refused by some local producers who have their supply contracted for until Jan. 1. The price is \$2.50 a ton. Steel manufacturers are still buying heavily for pickling purposes.

Zinc chloride is extremely active. One local producer reports sending a million pounds in July to a customer who formerly bought only 1,500,000 lb. in a year. The price is 3 $\frac{3}{4}$ c. a lb. on contract and 4c. on the open market for 50 per cent.

Zinc oxide continues very strong with the demand greater than the supply. Production has been increased locally, but orders are still hard to fill. The demand for low-leaded and lead free is strong, but not quite as strong for high-leaded. Prices remain the same.

Barytes continue in heavy demand at same prices, but an ultimate advance is declared inevitable, by local producers. Unusually heavy business by paint manufacturers is reflected strongly in the barytes field. Prices for water-floated barytes remain at \$23 to \$25 a ton, including barrels; \$21.50 to \$23.50 in bags, extra charge being made for the bags; all prices f.o.b. mills in carload lots.

Chicago, July 28, 1919.

Marked advances in a few items of heavy chemicals and circus stunts on the part of most items in the line of naval stores have made the Chicago market interesting for the past two weeks. High prices seemingly have no deterrent effect on sales, all dealers reporting business far in excess of normal.

Heavy Chemicals—Caustic soda and soda ash are holding firm at quotations established three weeks ago, solid caustic bringing 3c. to 3 $\frac{1}{2}$ c., and granulated 4c., soda ash 2c. The threatened advance in bleaching powder (calcium hypochlorite) has not occurred, price remaining firm at 2c. with good demand.

Niter cake (sodium bisulphate) shares in the prosperity of sulphuric acid, quantities having been placed under contract by the steel interests at about \$4 a ton. Spot sales in small lots are bringing a considerably higher price. Sodium bichromate has advanced from 7 $\frac{1}{2}$ c. on the first of the month to 11 $\frac{1}{2}$ c. today, with apparently the end not yet in sight.

Potassium carbonate is still being quoted by some dealers as high as 22c., though several lots have changed hands at a much lower figure; but 17c. should probably be considered actual price today. Yellow potassium prussiate is another article that has gone up to a surprising degree, sales being effected this week at 65c. against an easy market of 35c. three weeks ago.

Vegetable Oils—Linseed oil struck a record high figure in Chicago about ten days ago of \$2.73 in barrels, this figure holding but a short time, however. It is now quoted at \$2.48. The very complete tie-up of building operations now in effect here may cause some reduction, as local consumption will be seriously reduced. Other vegetable oils have remained steady, quotations of July 9th letter still holding good.

Flotation Oils, Naval Stores.—There seem to be no limits to the price heights which have been or may be reached in these lines. Turpentine heads the list with plenty of sales being effected at 1.36, and its habit of jumping not less than one cent a day seems to have become confirmed. Rosin is also high, grade WW being quoted at 21.60, F at 17.70, E at 17.45 and B at 16.50, delivered Chicago. Pine tar in barrels brings 35c. to 37c. and pine tar oil 38c. to 40c.

Ortho-nitro-benzidine	lb.	30	45
Ortho-nitro-toluol	lb.	27	40
Para-aminobenzol	lb.	1.25	1.50
Para-aminobenzonitrile	lb.	2.25	2.75
Para-dichlorobenzol	lb.	06	10
Paranitraniline	lb.	1.00	25
Paranitrobenzol	lb.	1.25	1.50
Paraphenylenediamine	lb.	2.25	4.00
Paratoluidine	lb.	1.50	2.75
Phthalic anhydride	lb.	1.25	2.15
Phthalic acid, U. S. P., drums (100 lb.)	gal.	2.25	1.10
Pyridin	gal.	2.50	3.75
Resorcinol, technical	lb.	6.50	7.75
Resorcinol, pure	lb.	1.25	1.50
Salicylic acid, U. S. P., in bbls (100 lb.)	lb.	10	15
Solvent naphtha, water white, in drums (100 gal.)	gal.	20	27
Sulphanilic acid, crude	lb.	25	24

Tolidine, mixed.....	lb.	1.75	—	2.50
Toluidine, mixed.....	lb.	44	—	80
Toluol, in tank cars.....	gal.	22	—	24
Toluol, in drums.....	gal.	23	—	30
Xylidine, drums, 100 gal.....	lb.	44	—	46
Xylol, pure, in tank cars.....	gal.	37	—	45
Xylol, pure, in tank cars.....	gal.	35	—	45
Xylol, commercial, in drums, 100 gal.....	gal.	23	—	27
Xylol, commercial, in tank cars.....	gal.	22	—	27

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow.....	lb.	\$0.44	—	\$0.45
Beeswax, refined, yellow.....	lb.	48	—	55
Beeswax, white pure.....	lb.	65	—	68
Carnauba, No. 1.....	lb.	90	—	90
Carnauba, No. 2, regular.....	lb.	75	—	85
Carnauba, No. 3, North Country.....	lb.	60	—	65
Japan.....	lb.	181	—	21
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb.	06	—	06
Paraffine waxes, crude, scale 124-126 m.p.....	lb.	071	—	081
Paraffine waxes, refined, 118-120 m.p.....	lb.	09	—	10
Paraffine waxes, refined, 128-130 m.p.....	lb.	11	—	12
Paraffine waxes, refined, 133-135 m.p.....	lb.	121	—	12
Stearic acid, single pressed.....	lb.	25	—	29
Stearic acid, double pressed.....	lb.	28	—	32
Stearic acid, triple pressed.....	lb.	30	—	32

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal.	\$0.78	—	68
Pine oil, pure, dist. in drums.....	gal.	45	—	33
Pine tar oil, ref., sp. gr. 1.025-1.035.....	gal.	65	—	65
Pine tar oil, ref., sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.....	gal.	34	—	72
Pine tar oil, thin, sp. gr. 0.965-0.990.....	gal.	27	—	48
Pine tar, ref., thin, sp. gr. 1.080-1.960.....	gal.	27	—	48
Turpentine, crude, sp. gr. 0.900-0.970.....	gal.	27	—	48
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....	gal.	27	—	48
Pinewood creosote, ref.....	gal.	27	—	48

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.....	280 lb.	\$16.75	—	\$17.25
Rosin E-I.....	280 lb.	17	—	18.75
Rosin K-N.....	280 lb.	22	—	22.25
Rosin W. G.-W. W.....	280 lb.	22	—	22.75
Wood rosin, bbl.....	280 lb.	17.25	—	19
Spirits of turpentine.....	gal.	1.25	—	1.27
Wood turpentine, steam dist.....	gal.	1.19	—	1.27
Wood turpentine, dest. dist.....	gal.	1.10	—	1.10
Pine tar pitch, bbl.....	200 lb.	8.25	—	8.50
Tar, kiln burned, bbl. (500 lb.).....	bbl.	12.5	—	13.50
Retort tar, bbl.....	280 lb.	13.75	—	14.50
Rosin oil, first run.....	gal.	81	—	91
Rosin oil, second run.....	gal.	83	—	93
Rosin oil, third run.....	gal.	85	—	95
Rosin oil, fourth run.....	gal.	88	—	110

Solvents

73-76 deg., steel bbls. (85 lb.).....	gal.	\$0.33	—	34
70-72 deg., steel bbls. (85 lb.).....	gal.	31	—	31
68-70 deg., steel bbls. (85 lb.).....	gal.	30	—	30
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal.	23	—	23

Crude Rubber

Parn—Upriver fine.....	lb.	\$0.54	—	\$0.55
Upriver coarse.....	lb.	31	—	33
Upriver cauchó ball.....	lb.	31	—	34
Plantation—First latex crepe.....	lb.	39	—	40
Rubbed smoked sheets.....	lb.	38	—	39
Brown crepe, thin, clean.....	lb.	34	—	35
Amber crepe No. 1.....	lb.	36	—	37

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls.....	lb.	\$0.19	—	\$0.21
Castor oil, AA, in bbls.....	lb.	21	—	23
China wood oil, in bbls.....	lb.	22	—	24
Cocoonat oil, Ceylon grade, in bbls.....	lb.	19	—	20
Cocoonat oil, Cochín grade, in bbls.....	lb.	21	—	22
Corn oil, crude, in bbls.....	lb.	22	—	24
Cottonseed oil, crude (f.o.b. mill).....	lb.	22	—	23
Cottonseed oil, refined, in bbls.....	lb.	27	—	28
Cottonseed oil, winter yellow.....	lb.	28	—	29
Linsed oil, raw, ear lops.....	gal.	2.22	—	2.22
Linsed oil, raw, tank cars.....	gal.	2.15	—	2.17
Linsed oil, boiled, ear lops.....	gal.	2.17	—	2.22
Olive oil, commercial.....	gal.	2.30	—	2.56
Palm, Lagos.....	lb.	173	—	18
Palm, bright red.....	lb.	17	—	18
Palm, Nixer.....	lb.	163	—	17
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	26	—	27
Peanut oil, refined, in bbls.....	lb.	29	—	30
Rapeseed oil, refined in bbls.....	gal.	1.60	—	1.60
Rapeseed oil, blown, in bbls.....	gal.	1.60	—	1.70
Soya bean oil (Manchurian), in bbls., N. Y.....	lb.	20	—	20
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	18	—	18

FISH

Winter pressed Menhaden.....	gal.	\$1.25	—	\$1.35
Yellow bleached Menhaden.....	gal.	1.27	—	1.37
White bleached Menhaden.....	gal.	1.29	—	1.38
Blown Menhaden.....	gal.	1.35	—	1.40

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated.....	ton	\$25.00	—	\$36.00
Barytes, off color.....	ton	20	—	25
Blanc fixe, dry.....	lb.	0.03	—	0.04
Blanc fixe, pulp.....	lb.	30	—	40
Casein.....	lb.	16	—	18
Chalk, English, extra light.....	lb.	05	—	07
Chalk, English, light.....	lb.	04	—	06

Chalk, English, dense.....	lb.	04	—	05
China clay (Kaolin), imported, lump.....	ton	25.00	—	35.00
China clay (Kaolin), imported, powdered.....	ton	30	—	40
China clay (Kaolin), domestic, lump.....	ton	10.00	—	20.00
China clay (Kaolin), domestic, powdered.....	ton	25.00	—	40.00
Fluorspar, acid grade, lump, f.o.b. mines.....	ton	11.00	—	15.00
Fluorspar, acid grade, powdered, f.o.b. mines.....	ton	330.00	—	335.00
Fuller's earth, domestic, powdered.....	ton	35.00	—	45.00
Fuller's earth, imported, powdered.....	ton	30.00	—	40.00
Pumice stone, imported.....	lb.	03	—	06
Pumice stone, domestic.....	lb.	02	—	03
Shellac, TN.....	lb.	—	—	—
Shellac, D. C.....	lb.	—	—	—
Shellac, V. S. O.....	lb.	—	—	—
Shellac, Diamond I.....	lb.	—	—	—
Shellac, orange, fine.....	lb.	—	—	—
Shellac, orange, superfine.....	lb.	1.10	—	1.15
Shellac, bleached, bone dry.....	lb.	95	—	95
Shellac, bleached, fresh ground.....	lb.	1.35	—	1.35
Soapstone.....	ton	15.00	—	25.00
Talc, domestic.....	ton	16.00	—	60.00
Talc, imported.....	ton	55.00	—	60.00

Refractories

Following prices are f.o.b. works:

Chrome brick.....	net ton	90-100 at Chester, Penn.
Chrome cement.....	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay.....	net ton	35-45 at Clearfield, Penn.
Clay brick, 2nd quality.....	net ton	30-35 at Clearfield, Penn.
Magnesite brick, 9 x 4 1/2 x 2 1/2 in.....	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4 1/2 x 2 1/2 in.....	net ton	80-90 at Chester, Penn.
Silica brick.....	net ton	41-45 at Mt. Union, Penn.

Ferroalloys

All prices f.o.b. works.

Ferro-chrome-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$220.00	—	—
Ferro-chrome, per lb. of Cr. contained, 6-8%.....	lb.	32	—	\$0.40
Carbon.....	lb.	70	—	—
Ferro-manganese, 70-80% Mn.....	gross ton	100.00	—	125.00
Spirogleisen, 16-20% Mn.....	gross ton	30.00	—	50.00
Ferro-nickel, 50% Ni.....	gross ton	85.00	—	115.00
Ferro-silicon, 50% Si.....	gross ton	150.00	—	175.00
Ferro-tungsten, 70-80% W.....	gross ton	45.00	—	60.00
Ferro-uranium, 35-50% of U.....	lb.	7.00	—	7.00
Ferro-vanadium, 30-40% of V.....	lb.	5.50	—	7.00

Resales and overstocks make above prices approximate.

Ores and Semi-finished Products

Chrome ore, 35-40% Cr. O ₂	unit	\$0.60	—	—
Chrome ore, 48% and over.....	unit	80	—	—
Coke, foundry, f.o.b. mines.....	net ton	5.25	—	\$3.50
Coke, furnace, f.o.b. mines.....	net ton	4.50	—	5.00
Petroleum coke, f.o.b. Atlantic seaboard.....	net ton	16.00	—	16.50
Fluorspar, gravel, f.o.b. mines.....	net ton	20.00	—	25.00
Manganese ore, 45% Mn and over.....	unit	60	—	65
Manganese ore, chemical (MnO ₂).....	gross ton	60.00	—	60.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂	lb.	75	—	85
Tungsten, Scheelite, 60% WO ₃ and over per unit of WO ₃	unit	9.00	—	12.00
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃	unit	7.00	—	10.00
Uranium oxide, 96%.....	lb.	—	—	—
Vanadium pentoxide, 99%.....	lb.	6.00	—	—
Pyrites, foreign, lump.....	unit	15	—	—
Pyrites, foreign, fine.....	unit	14	—	—
Pyrites, domestic, fine.....	unit	14	—	—
Ilmenite, 50% TiO ₂	net ton	30.00	—	—
Rutile, 95% TiO ₂	net ton	200.00	—	200.00
Carnotite, minimum 25% U ₂ O ₅ , per lb. of U ₂ O ₅	lb.	2.75	—	3.00

Resales and overstocks make above prices approximate.

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

Portland cement, at dock, without bags.....	bbl.	\$2.30	—	—
Lump lime, common, including container.....	300 bbl.	2.65	—	—
Common brick, at dock.....	M.	15.00	—	—
Hollow building tile.....	M.	194.40	—	—
At factory, Perth Amboy, N. J., 8x12x12.....	M.	291.60	—	—
Yellow pine, 3x4 to 8x8, 20-24 ft. long.....	M.	40.00	—	—
Yellow pine, 3x4 to 8x8, 20-24 ft. long at Chicago.....	M.	39.50	—	—
Yellow pine, 3x4 to 8x8, 20-24 ft. long at St. Louis.....	M.	37.00	—	—
Roofing, tar felt (14 lb. per 100 sq. ft.).....	ton	21.00	—	—
Roofing, tar pitch (in 400-lb. bbl.).....	ton	21.00	—	—
Roofing, asphalt pitch.....	ton	34.00	—	—
Roofing, asphalt felt.....	ton	63.00	—	—
Roofing, slate-surfaced, per 100 sq. ft. of 108 sq. ft. of.....	ton	15.00	—	—
Roofing, slate-finished shingles, 100 sq. ft. of.....	ton	5.00	—	—
Linsed oil, raw in barrels.....	gal.	2.15	—	—
Linsed oil, 5 gal. cans.....	gal.	2.28	—	—
Red lead, dry, 100 lb. keg.....	lb.	1.43	—	—
Red lead, in oil, 100 lb. keg.....	lb.	1.43	—	—
Red lead, dry, 5 lb. cans.....	lb.	1.15	—	—
Red lead, in oil, 5 lb. cans.....	lb.	1.61	—	—
White lead, dry and in oil, 100 lb. keg.....	lb.	1.33	—	—
White lead, dry and in oil, 25 and 50 lb. kegs.....	lb.	1.33	—	—
White lead, dry and in oil, 5 lb. cans.....	lb.	1.15	—	—

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....	100 lb.	\$2.45	—	—
Angles, 3 to 6-in., 4-in. thick.....	100 lb.	2.45	—	—
Tees, 3-in. and larger.....	100 lb.	2.45	—	—
Plates.....	100 lb.	2.66	—	—
Rivets, structural, 4-in. and larger.....	100 lb.	4.20	—	—
Sheets, conehead for boilers, 4-in. and larger.....	100 lb.	4.30	—	—
Sheets, No. 28 thick.....	100 lb.	4.15	—	—
Sheets, No. 10 blue annealed.....	100 lb.	3.55	—	—
Sheets, No. 28 galvanized.....	100 lb.	5.70	—	—

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; add 50c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

MONTGOMERY—The Alabama Georgia Syrup Co., Jones St., plans to build a 2-story, 95 x 170-ft. factory on North Court St. Estimated cost, \$50,000. Okel & Cooper, Vandiver Bldg., architects.

Arizona

JOHNSON—The Keystone Copper Co., Newton, Kan., will erect a 100-ton mill, using the flotation and concentration process, at its copper mines six miles east of Johnson.

California

ELRIDGE—The State of California is having plans prepared by the State Department of Engineering, Sacramento, for rebuilding the sewage disposal plant at Sonoma State Hospital, to include an Imhoff tank and sprinkling filter. Estimated cost, \$20,000.

NORTH BERKELEY (Berkeley P. O.)—The East Bay Water Co., Oakland, plans to build a filtration plant. C. H. Wilhelm, Oakland, engineer. Hazen, Whipple & Fuller, 30 East 42nd St., New York City, N. Y., architects.

SACRAMENTO—The city voted \$1,800,000 bonds for the construction of a filtration plant and water system. Noted May 1.

WATERMAN—The State of California is having plans prepared by the State Engineering Department, Sacramento, for the construction of a new sewage disposal system at the Preston School of Industry, to include an Imhoff tank and sprinkler system. Estimated cost, \$14,000.

YOUNTVILLE—The State of California is having plans prepared by the State Engineering Department, Sacramento, for the construction of a sewage disposal plant at the Veterans' Home, to include an Imhoff tank and sprinkling filter. Estimated cost, \$10,000.

Colorado

GATEWAY—The Carollite Mining Co. plans to build a reduction plant here. Estimated cost, \$25,000.

Connecticut

JEWETT CITY—The Ashland Cotton Co. plans to build a 1-story, 150 x 130-ft. mill. Work will be done by day labor. Estimated cost, \$65,000.

NEW HAVEN—The State Board of Health, Capitol, Hartford, will erect a laboratory on Huntington St. Estimated cost, \$100,000.

Florida

MIAMI—The city plans to build a filtration plant. State Board of Health, Jacksonville, preparing plans.

TAMPA—The city plans to build a filtration plant. State Board of Health, Jacksonville, preparing plans.

Illinois

CHICAGO—The Century Rubber Works, 1346 Rawson St., plans to build a 3-story, 200 x 350-ft. factory on La Salle St. Estimated cost, \$200,000. Osborn Engineering Co., 2848 Prospect Ave., Cleveland, Ohio, engineer.

FREEPORT—The Furst-McNess Co. has awarded the contract for the construction of a 6-story, 75 x 160-ft. reinforced-concrete chemical factory, to H. W. Holst & Co., State Bank Bldg., Rock Island. Estimated cost, \$125,000.

Kansas

RUSSELL—The city plans to build a complete sewerage system and disposal plant. Estimated cost, \$60,000. Black & Veatch, International Bldg., Kansas City, Mo., engineers.

Maryland

HIGHLANDTOWN (Baltimore P. O.)—The Jones & Lamb Co., Pennsylvania and Fulton Aves., Baltimore, has awarded the contract for remodeling the plant of the Monumental Brewery Co. at 7th and Lombard Sts. into a meat packing plant and oil refinery, to the Consolidated Engineering Co., 243 Calvert Bldg., Baltimore. Estimated cost, \$500,000.

Michigan

DETROIT—The C. B. Bohn Foundry Co., Hart Ave., has awarded the contract for the construction of a 1-story, steel, brick and concrete addition to its core room and a 30 x 30 ft. brick and reinforced-concrete gas house with settling tanks, gas and air line tunnels and ducts, to C. H. Reisdorf, 753 Greenwood Ave.

DETROIT—The Fisher Body Corp., Piquette Ave., will soon award the contract for the construction of a 6-story, 155 x 581-ft. paint shop on St. Antoine St. and Piquette Ave. Smith, Hinchman & Grylls, 710 Washington Arcade, engineers.

Massachusetts

MILITINEAGUE—The Strathmore Paper Co. plans to build a factory here. Estimated cost, \$100,000.

WORCESTER—The Sewer Commission plans to install an Imhoff sewerage purification system. Estimated cost, \$250,000. Address M. Gault, commissioner.

Minnesota

MINNEAPOLIS—The Northwestern Distilled Water Co., 627 Bassett Pl., will soon award the contract for the construction of a 1-story, 30 x 50-ft. distilled water factory at North Minneapolis. Estimated cost, \$500.

ST. PAUL—Charles Weinhausen & Co., 450 Jackson St., plans to construct a 1-story, 110 x 230-ft. reinforced-concrete paper factory and office building on 14th St., near Pine St. Estimated cost, \$200,000.

Missouri

MACON—The city has awarded the contract for the construction of a sewage disposal plant, to W. McClurken, 3807 Westminster St., St. Louis. Estimated cost, \$16,000.

ST. LOUIS—The T. J. Sayman Co., 2117 Franklin Ave., has awarded the contract for the construction of a 1-story, 50 x 154-ft. soap factory at 2131 Franklin Ave., to the Sayman Real Estate & Investing Co., 2117 Franklin Ave. Estimated cost, \$10,000.

Nebraska

LINCOLN—The Lincoln Paint & Color Co. plans to construct a 2-story, 40 x 130-ft. factory at 811 M St. Fliske & McGinnis, 533 Bankers' Life Bldg., architects. Estimated cost, \$250,000.

New Jersey

IRVINGTON (Newark P. O.)—The Jennings Silver Co., 309 Nye Ave., has awarded the contract for the construction of a 2-story, 40 x 90-ft. factory, to the Standard Building Block Co., 21st St. Estimated cost, \$10,000.

JAMESBURG—The Department of Architecture, 142 West State St., Trenton, received lowest bid for the construction of a sewerage system at the State Home for Boys, from G. L. Robinson, 29 East 28th St., New York City, N. Y. Plans include a 54-ft. stone filter bed, sludge bed, etc. Estimated cost, \$10,000. Noted July 1.

NEWARK—The Patton Paint Co., Chester Ave., has awarded the contract for the construction of a 2-story, 61 x 121-ft. factory, to C. R. Heddon Co., Prudential Bldg., at \$63,465. Noted June 15.

SALEM—The city will soon award the contract for the construction of a filtration plant, including a coagulating basin, chemical house, filter house and all appliances. W. H. Boardman, 429 Walnut St., Philadelphia, engineer.

TRENTON—The Thermoid Rubber Co., Whitehead Rd., plans to build a 3-story, 100 x 270 ft. plant, here. Estimated cost, \$150,000. Osborn Engineering Co., 814 Prospect Ave., Cleveland, Ohio, engineer.

New York

COLIQUES—James E. Glendhill, 541 West 34th St., New York City, has awarded the contract for the construction of a 2-story, 100 x 100-ft. brick and steel wall paper mill, to C. P. Boland Construction Co., 30 4th St., Troy. Estimated cost, \$250,000.

KINGS PARK—The State Hospital Commission, Capitol, Albany, will soon award the contract for extending the sewage disposal plant at the State Hospital, here. Estimated cost, \$11,800.

LITTLE FALLS—The Barnes Leather Co., 598 East Mill St., plans to build a 3-story addition to its plant. Estimated cost, \$35,000. E. L. White, superintendent.

NIAGARA FALLS—The Niagara Falls Gas & Electric Light Co., 306 Niagara Works, Ellicottway, will soon award the contract for the construction of a new gas plant at Buffalo Ave. and 22nd St. Estimated cost, \$200,000. A. H. Merritt, superintendent.

NUNDA—Peck & Pratt, Inc., have purchased a site and will erect a condensed milk plant. Laboratory equipment will be installed in same. Estimated cost, between \$35,000 and \$50,000.

TROY—The Henssler Polytechnic Institute plans to build a 2-story addition to the William Weichtman Walker Laboratory. Estimated cost, \$175,000. Address Palmer C. Hackett, president.

North Dakota

NEW ROCKFORD—The city plans to install a water softening plant. Estimated cost, \$20,000.

Ohio

ASHLAND—The Ashland Tire & Rubber Co. plans to build a 2-story, 75 x 125-ft. rubber plant. Estimated cost, \$90,000. Osborn Engineering Co., 2818 Prospect Ave., Cleveland, engineer.

ASHLAND—The Faultless Rubber Co. plans to build a 3-story, 60 x 160-ft. factory addition here. Estimated cost, \$75,000. Osborn Engineering Co., 2848 Prospect Ave., Cleveland, engineer.

BARNESVILLE—Morris Knowler, engineer, Jones Law Bldg., Pittsburgh, has submitted a report to the borough for the construction of a sewerage system and a disposal plant. Estimated cost, \$100,000. People now running campaign to raise the necessary funds.

CLEVELAND—The Atlantic Foundry Co., 7510 Morgan Rd., plans to build a 1-story, 26 x 36-ft. foundry addition. Estimated cost, \$50,000.

CLEVELAND—The Crescent Brass Manufacturing Co., 8410 Lake Ave., plans to rebuild the 3-story, 30 x 120-ft. factory which was recently destroyed by fire. Estimated cost, \$50,000.

COLUMBUS—The Columbus Tire & Rubber Co., Dayton Bldg., has awarded the contract for the construction of a 2-story, 75 x 300-ft. rubber factory on the west bank of the Olentangy River, to Cummins & Blair Co., Cleveland. Noted June 15.

CLEVELAND—The McElrath Tire & Rubber Co., 820 Union Bldg., plans to construct a 2-story, 60 x 200-ft. factory on East 131st St. Estimated cost, \$80,000.

CLEVELAND—Benjamin Moore & Co., 1514 Marquette Ave., plans to build a 1-story, 60 x 100-ft. paint factory on East 71st and Grant Ave. Estimated cost, \$60,000.

CLEVELAND—The National Malleable Castings Co., 7706 Platt Ave., plans to build a 3-story, 49 x 52-ft. research laboratory at 10469 Quincey Ave. Estimated cost, \$50,000.

MARION—The American Malleable Castings Co. plans to build a 1-story, 60 x 70 ft. and 70 x 75-ft. addition to its foundry here. Estimated cost, \$30,000. Osborn Engineering Co., 2848 Prospect Ave., Cleveland, engineer.

MIDDLETOWN—The American Latex Mills Co. will build an entire new 4 x 8 ft. and equal same at cost of \$350,000. Work will be done by day labor.

WARREN—The D. M. Ford Tire Co., Engineers Bldg., Cleveland, plans to construct a 3-story, 60 x 120-ft. rubber plant. Estimated cost, \$75,000.

Oklahoma

IDAHEE—The city will receive bids until Aug. 4 for the construction of a complete sewerage system, including main and lateral sewers and a sewage disposal plant. Johnson & Benham, Firestone Bldg., Kansas City, Mo., engineers. Noted Feb. 1.

Oregon

PORTLAND—The Portland Gas & Coke Co., 234 Yamhill St., plans to build a 1-story, 63 x 70-ft. and 32 x 94-ft. factory, or Linton Rd. Estimated cost, \$10,000.

Pennsylvania

LANCASTER—The city has retained Gannett, Seelye & Fleming, engineers, 204 Locust St., Harrisburg, to prepare plans and supervise construction of a sewage disposal plant.

Rhode Island

CUMBERLAND (Manville P. O.)—The city plans to construct a new sewerage system. Estimated cost, \$150,000. O. Perry Sarle, 146 Westminster St., Providence, engineer.

South Carolina

BARNWELL—The city plans an election to vote on \$50,000 bonds for the construction of a sewerage system, including a septic tank. Tomlinson Engineering Co., 1003 Loan & Exchange Bank Bldg., Columbia, engineer.

LAKE CITY—The city will receive bids about Aug. 20 for the construction of a sewerage system, gravity type septic tank disposal. Estimated cost, \$60,000. Tomlinson Engineering Co., 1003 Loan & Exchange Bank Bldg., Columbia, engineer.

Utah

LEHI—The Utah County School Board will receive bids until Aug. 15 for the construction of a 2-story, 137 x 160-ft. high school. A chemical laboratory will be installed. Estimated cost, \$100,000. Warren Treganza, Utah Savings & Trust Bldg., Salt Lake City, engineer.

West Virginia

HUNTINGTON—The Standard Ultramarine Co., 5th Ave. and 25th St., plans to build a 3-story, 80 x 100-ft. laboratory for the manufacture of bluing, on 24th St. Estimated cost, \$25,000.

Wisconsin

PESHIGO—The Peshigo Pulp & Paper Co. plans to build a 2-story, 70 x 178-ft. pulp and paper factory on Main St. Estimated cost, \$55,000. J. J. Smith, resident, L. A. DeGuerre, Peshigo Rapids, engineer.

TWO RIVERS—Jul & Smith, Imig Bldg., Sheboygan, is preparing plans for a 2-story, 60 x 190-ft. brick and concrete aluminum factory on Main St. Estimated cost, \$30,000. Owner's name withheld.

Ontario

BURLINGTON—The city will soon award the contract for the construction of a sanitary sewerage system. Estimated cost, \$150,000. Chipman & Power, Mail Bldg., Toronto, engineers.

DUNDAS—A. W. Dzuske, chairman of the Sewer Committee, received bids for the construction of sewage disposal works, including sprinkler system, etc., from Curran & Clomont, Dundas, \$152,032; Canadian Engineering & Construction Co., Toronto, \$216,533; Connolly-Agnew Co., Toronto, \$228,222. Noted June 15.

FORD CITY—The Imperial Oil Co., 156 Church St., Toronto, has awarded the contract for the construction of a refinery to the Wescott Contracting Co., Windsor. Estimated cost, \$100,000.

TORONTO—The city plans to build a pumping station and filtration plant at Victoria Park. Estimated cost, \$2,000,000. R. C. Harris, City Hall, engineer.

TORONTO—The city plans to build an experimental activated sludge unit. Estimated cost, \$50,000. R. C. Harris, City Hall, engineer.

TORONTO—The Northern Aluminum Co., 158 Sterling Rd., will soon award the contract for the construction of a 10-story, 60 x 280-ft. reinforced concrete factory for the manufacture of aluminum ware and wire. Estimated cost, \$300,000. C. P. Turner, 1005 Lindsay Bldg., Winnipeg, Manitoba, engineer.

Quebec

RED MILL—The Canada Paint Co., 572 William St., Montreal, will receive bids in August for the construction of a 3-story, 40 x 60-ft. factory to replace the one which was recently destroyed by fire. Estimated cost, \$42,000.

Coming Meetings and Events

THE AMERICAN CERAMIC SOCIETY will hold a meeting in Chicago, Sept. 24. THE AMERICAN CHEMICAL SOCIETY will hold its Fall meeting in Philadelphia, Pa., Sept. 2-6 inclusive.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its Fall meeting in Chicago, Sept. 23-25 inclusive.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its 1919 convention in Philadelphia, Sept. 29 to Oct. 4.

THE AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition of gas appliances and apparatus at the Hotel Pennsylvania, New York, October 13 to 18.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its Fall meeting in Chicago, Ill., Sept. 22-27.

THE AMERICAN STEEL TREATERS' SOCIETY will hold its first annual convention in Chicago, Ill., Sept. 22-27.

THE FIFTH NATIONAL EXPOSITION OF 'CHEMICAL INDUSTRIES' will be held in Chicago, Ill., Sept. 22-27 inclusive.

THE INSTITUTE OF METALS DIVISION of the A. I. M. E. will hold its next meeting in Philadelphia, Pa., Sept. 29 to Oct. 4.

THE INSTITUTE OF METALS will hold its Autumn meeting in Sheffield, England, Sept. 24-25.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its Fall meeting in Chicago from Sept. 24 to 27.

Industrial Notes

MESSRS. T. L. WHEELER AND J. C. WOODRUFF, both of whom held the rank of Major in the Chemical Warfare Service, have associated themselves together for business and chemical engineering research work, investigation of processes, design and managing of chemical plants and the organization of technical staffs for chemical concerns. Special attention will be given to the treatment of animal and vegetable fats and oils, electroplating and the electrolytic refining of metals, corrosion and active iron of charcoal. Offices have been established at 280 Madison Ave., New York City.

Lieut.-Commander John L. Murrie, formerly of the New York Edison Co. and Capt. Edward F. McCrossin, formerly of the McCrossin Engineering Co. have been relieved of active duty in the navy and army respectively and have organized the firm of Murrie & Co. with offices at 74 Broadway, New York. Murrie & Co. will conduct a general consulting business and will give special attention to financial reports on gas and coal-by-product plants. This United Fuels Corp. has established a sales office at 35 Montgomery St., San Francisco, under the direction of the Western Sales & Engineering Corporation. In addition to this office the company's branch on the West coast is also taken care of by Kennard & Pierce of Los Angeles, and the United Iron Works, Spokane, Wash. These offices, together with the older ones in Salt Lake City, Chicago and New York, will provide a complete service in this country.

THE NEW JERSEY CONCENTRATING CO., 66 York St., Jersey City, N. J., has established a plant for the electromagnetic concentration of low-grade tungsten ores. Impurities such as tin and copper are removed almost completely with an excellent recovery of the tungsten. The plant includes equipment for crushing, sampling and magnetic separation. A sworn sampler and weigher of Messrs. Ledoux & Co. is always on the premises. Proximity to the waterfront and railroad yards gives excellent facilities for loading and unloading ore. Storage space is provided for customers' use.

THE ELECTRIC FERNACE CO., Alliance, Ohio, announces that it has installed a battery of two Baily electric furnaces at the Capital Brass Works, Detroit, Michigan. These furnaces are of the standard 105-kw. tilting type, with hearth capacities

of 1500 lb. each. They will be used for melting yellow brass scrap and borings, in the foundry. The Buick Motor Co., Flint, Mich., has purchased its second Baily furnace for melting phosphor bronze. This furnace is of the tilting type, rated at 1500-lb. hearth capacity and an electrical capacity of 105 kw. It is also announced that the Akron Bronze & Aluminum Co., Akron, Ohio, has installed a 20-kw. rectangular tilting type Baily electric furnace in its jobbing foundry. This furnace has a hearth capacity of 300 to 500 lb. and will be used for a wide variety of compositions. Heats will range from 100 to 500 lb. and will include gun metal, phosphor bronze, red and yellow brass.

THE BLAW-KNOX CO., Pittsburgh, announces the appointment of Mr. Frank O. Leitzell as engineer-salesman in the sheet and tin mill specialties department. Mr. Leitzell was formerly assistant to the general manager of the H. K. Porter Co., Pittsburgh. This company recently completed and formally presented to the children of its employees a playground at Broken Run, Pa. The playground is complete in every detail and is intended for the employees themselves as well as their children.

A Thought on The General Unrest

SPEAKING in London to a group of American technical journalists who were the luncheon guests of Lord NORTHCLIFFE, Mr. W. L. HICHENS, managing director of Cammell Laird & Co., Ltd., pronounced some exceptionally sane views on the subject of employer and employee, production and wages, strikes and lockouts. They recur to mind with peculiar force in view of the epidemic of unrest which has recently manifested itself almost throughout the United States. Admitting that his company would like to maintain or even increase wages and reduce working hours, Mr. HICHENS recognized that this could be done only by increasing production, which, in turn, could be accomplished only by improving mechanical devices and by discontinuing the evil practice of restricting output. But it was in relation to labor strikes and inordinate capital profits that his words rang true when he declared that neither labor nor capital had any right "to hold the community up to ransom and pillage them by means of strong combinations." The expression is worth sober reflection by those who apparently have forgotten that "Industry ought to be at the service of the community as a whole," and that no minor class should be allowed to dictate the terms and conditions under which it will play its part in the national life. We cannot believe that the community as a whole is growing in sympathy with groups of men who, either by extortion or by threats of violence, gain an undue advantage over the balance of their fellows. Reaction must set in sooner or later, and in the long run the part of prudence must be to retain the esteem of the public.

Andrew Carnegie, Steel Manufacturer

ANDREW CARNEGIE, Laird of Skibo, philanthropist and American steel manufacturer, died on August 11 in his eighty-fourth year. Much might be said of his public and private benefactions, setting a new world record, his efforts to promote world peace and his intelligent love of art, but these things are well known. How and why he became the greatest steel maker in the world is particularly worth considering. His very first venture in business gives us one key. He had advanced from bobbin boy to stoker, to bill clerk, to messenger boy and then to telegraph operator, when his employer, Col. THOMAS A. SCOTT, division superintendent of the Pennsylvania Railroad, secured him the opportunity to subscribe for ten shares of Adams Express Co. stock at \$60 a share. The Carnegie home was mortgaged for \$500 and Colonel SCOTT helped young

CARNEGIE on the balance. In the industrial depression of 1893-98, when iron mills had failed right and left, it was said that every bank in Pennsylvania held Carnegie paper. Of all producers the Carnegie Steel Co. was the most successful in financing the change from wrought iron to steel.

Easily ANDREW CARNEGIE'S greatest asset was his ability to judge men, and in this his instinct was unerring. At a dinner in Cleveland Mr. CARNEGIE remarked he would like to have the epitaph: "Here lies a man who knew how to get around him men smarter than himself." The Associated Press in its dispatches left out the word "him" and thus set the newspaper paragraphers gasping. It was a matter not merely of getting smart men but of putting them in precisely the most appropriate job. In any business, therefore, Mr. CARNEGIE would have succeeded, but the steel business presented the finest opportunity.

ANDREW CARNEGIE himself said, "Pioneering doesn't pay"; yet in a measure he was a great pioneer. He knew when it was profitable to adopt the new method or the new device. In SWANK'S "Iron in All Ages" there is a list of first producers of bessemer steel in the United States. Carnegie Bros. & Co., Ltd., stand No. 11 in that list, with their first blow August 25, 1875, two 7-ton converters. Twenty years or so later basic open-hearth steel had been made at many works in the United States, but then the Carnegie Steel Co. adopted the process on a large scale. Quick to seize commercial opportunities, the company secured from Alabama much of the pig iron early used in the process, under freight rates that were neither printed nor fit to print.

As the United States was taking front rank in steel production, foreign producers experienced no difficulty in seeing that the key to the success achieved was tonnage outputs. Of that religion ANDREW CARNEGIE was the high priest. It has been related that Capt. WILLIAM JONES, one of the greatest mill managers of all time, would step into CARNEGIE'S office and with pride lay before him a new tonnage record, to which CARNEGIE: "That's fine! That's fine! Can't you do better next week?" When CARNEGIE remarked to JONES what a relief he felt when New York's sky line faded from view as he sailed abroad JONES rejoined: "And you've no idea what a relief it is to us!"

That the Homestead strike of 1892 carried the low tariff political party into power was generally recognized. It was only the psychological channel through which the event operated that was open to discussion. The fairest judgment seems to be that it was not that the voter regarded the tariff as a failure in producing high wages but that the eyes of the Western voters

were opened to the high wages offered and still not acceptable. The real contest was on limitation of output. The Amalgamated Association held out for its tonnage rates when output was increased, whereby improved machinery could not earn what it was entitled to. The American steel industry would not be near where it is to-day if the Amalgamated Association had won that contest, and the total payrolls of the industry would be much less than they are.

In selling steel Mr. CARNEGIE's ability was directly employed. For operating mills and conducting other operations he picked out men, but for years the sales policy was his own. One of his inventions was the sales arrangement that survives to this day as the contract sometimes opprobriously referred to as the "blanket" or "option" contract. He tied up large consumers with larger tonnages than they thought they would need, assuring them they would be taken care of and the contract would not be enforced to their disadvantage. Price agreements he did not keep, nor did the other parties. He played the game as it was being played in those days, more successfully and more fairly than the others.

As they are recalled in these present times some of ANDREW CARNEGIE's methods seem different from those employed to-day, but it would be idle to assume that if he were living his business life now he would not be the most modern of the modern.

European Opinion Regarding Mexico

SECOND in importance only to the solution of domestic problems is the settlement of the Government's affairs with Mexico. If press reports are to be accepted, we may believe that the Mexican situation is about to receive official attention in Washington, with the moral backing of the principal nations of Europe. It has been no secret for some time that English sentiment has been strongly in favor of the exercise of a firm and just policy in our relations with Mexico; and if the President returns with the same impressions that other Americans receive abroad, he knows that Europe thinks we have dawdled along in our Mexican policy to the point where patience loses its virtuous qualities and becomes a byword.

On numerous occasions in the capitals of Europe, Americans have been reminded of their obvious duty in Mexico, seeing that the Monroe Doctrine prevents European nations taking a hand in American affairs. Another item tending to influence European opinion against Mexico is the unquestionable pro-German bias shown by our southern neighbor during the war, particularly in its early stages before propaganda for the truth bore fruit. Again, refusal of Mexico's request for membership in the League of Nations may be taken as a foreshadowing of European opinion on Mexico's unsatisfactory relations with other nations.

On the whole, it would seem as though all the signs point toward early settlement in some form of the demoralizing conditions that have existed for almost a decade. Whether by benevolent intervention, as in the case of Cuba, or more forcefully, in a way that Mexicans would understand, we feel that the United States owes it to her citizens and the rest of the civilized world to take steps to end an intolerable and almost farcical condition. Opinion is crystallizing through

the National Association for the Protection of American Rights in Mexico, which seeks not only protection of American life and property but believes that it can also render a service to the Mexican people, who undoubtedly suffer from the chaos that has prevailed for so many years. Congressional action is indicated in resolutions recently introduced in the House and Senate relative to American claims for damages filed with the State Department, the status of our relations with Mexico, and the use of military force to protect American life and property in Mexico. With an aroused public opinion calling for official action, we have all the elements necessary for an early settlement.

Labor Research And Scientific Control

AT ITS Atlantic City meeting the American Federation of Labor adopted the following preamble and resolution:

Whereas scientific research and the technical application of results of research form a fundamental basis upon which the development of our industries, manufacturing, agriculture, mining and others, must rest; and

Whereas the productivity of industry is greatly increased by the technical application of the results of scientific research in physics, chemistry, biology and geology, in engineering and agriculture, and in the related sciences; and the health and well-being not only of the workers but of the whole population as well are dependent upon advances in medicine and sanitation so that the value of scientific advancement to the welfare of the nation is many times greater than the cost of the necessary research; and

Whereas the increased productivity of industry resulting from scientific research is a most potent factor in the ever-increasing struggle of the workers to raise their standards of living, and the importance of this factor must steadily increase, since there is a limit beyond which the average standard of living of the whole population cannot progress by the usual methods of readjustment, which limit can only be raised by research and the utilization of the results of research in industry; and

Whereas there are numerous important and pressing problems of administration and regulation now faced by Federal, State and local governments, the wise solution of which depends upon scientific and technical research; and

Whereas the war has brought home to all the nations engaged in it the overwhelming importance of science and technology to national welfare, whether in war or in peace, and not only is private initiative attempting to organize far-reaching research in these fields on a national scale, but in several countries governmental participation and support of such undertakings are already active; therefore be it

Resolved, By the American Federation of Labor in convention assembled, that a broad program of scientific and technical research is of major importance to the national welfare and should be fostered in every way by the Federal Government, and that the activities of the Government itself in such research should be adequately and generously supported and extended; and the work may be greatly strengthened and extended; and the secretary of the Federation is instructed to transmit copies of this resolution to the President of the United States, to the President pro tempore of the Senate, and to the Speaker of the House of Representatives.

This is an illuminating document, and we wish we could feel sure that the whole Federation were behind it. Without doubt it is a record of the aspirations of some of their earnest and conscientious leaders who have vision ahead of their day and generation. And it was voted through as the official expression of that great body.

The preamble contains certain principles which are more progressive than those which usually emanate from the councils of labor or those of manufacturing associations. We call attention to the statement that the development of our industries is based upon scientific research and its applications, and the merit of increasing the productivity of labor by this scientific control. It points out the "ever-increasing struggle of workers to raise their standard of living"—which is wholly in accord with their right to life, liberty and the pursuit of happiness—and it admits that under the present methods of strike and destruction the laborer does not raise himself very much after all. It holds that those who work with their hands may more effectively come into their own through scientific research. The men who framed this resolution recognize that under such research and control, workers will be called upon to meet the situation by sharper lookout and keener observation; that under the new conditions they will have to do more thinking than now, and they are ready for the new tasks.

This is the big vision, and it opens the door to democracy in industry, which is impossible when the laborer is interested only in his pay and the employer only in getting the work done. Under real scientific control and operation the men remain men; they cease to become "hands." The administrative head knows the need of variety of work to keep up the thinking capacity, and the greater value of men who can think over those who cannot think. And where men do think about their work and how to improve it, they do so to their own greater joy and well-being.

It is not to be expected that the changelings and unwilling workers and miscellaneous incompetents may be found among these well-favored men who do difficult and skilled work. Some provision will have to be made for the stupid so that the intelligent may be able to do what they can do—and what the stupid cannot. The able men who drew this resolution must have foreseen some reasonable segregation between complete and partial men in industry.

Scientific control in its best sense is impossible unless all parties to it are honest, unless they are men who keep their word, who fulfill their contracts and whose sense of responsibility is such that they recognize their obligations to the public as well as to their immediate associates. The defective employer has been justly held up to scorn and contumely and we hope his day may soon pass. We have no sympathy for him. But it is also fair to say that those members of labor unions who are constantly calling for lower costs of living and at the same time fomenting strikes that increase these costs beyond the meanest tricks of the worst profiteers are not developed enough in intelligence or advanced enough in character to participate in this democracy in industry that should follow true scientific control. They are, to put it in plain words, not good enough.

Here and there already we find an establishment in which everybody strives for progress and each one tries to keep ahead of his job; and it is a joy to visit it! And when we find every man making a companion of his daily task and doing his best with it and where the opportunity is really open to each man to advance to the limit of his capacity, we think we begin to sense the Golden Rule of Industry.

War Department Deserts Chemical Warfare Service

PROPOSERS of the Chemical Warfare Service can appreciate the trials of JON which led him to aver that "The thing which I greatly feared is come upon me"; for Chemical Warfare Service is to be disbanded, as we feared, and its functions are to be turned over to the tender ministrations of the Engineer Corps. The Army, speaking professionally, is against continuing the Service, just as the Army, professionally, was a close corporation, so far as Reserve Officers were concerned. Heaven alone knows, however, what the Army would have done without either or both of them. It is true that the Chemical Warfare Service probably did not cut a fine military figure, but it brought to bear on the war a knowledge of things unknown to the Army and which will continue to be a closed book if the Service is abandoned as recommended. The Chemical Warfare Service also was short on "military stuff," which is the life of the Army, but in this regard civilians will sympathize with the Reserve Officer who protested against "this military stuff in time of war" when he found it handicapped his operations.

Nevertheless the War Department, with a fine disregard for the future, is pursuing a plan which will practically throw into the discard a vast amount of knowledge, actual and potential, merely because the war is over. It is going counter to the recommendations of officers of high rank who believe thoroughly in the specialized organization of the Chemical Warfare Service, and who know how difficult it will be to recover the ground lost by inaction if the Service is abandoned. General SIBERT testified at a hearing before the Senate Committee on Military Affairs that in his opinion the Chemical Warfare Service could not be taken care of as well by the Corps of Engineers as by a separate bureau. He said he did not think engineer officers detailed for tours of duty on rivers and harbors, on fortifications and with troops, were qualified to handle chemical warfare. Lieutenant-Colonel, formerly Brigadier-General, AMOS A. FRIES told the committee that he had come back on temporary order from General PERSHING to present the need of maintaining the continuance of the Chemical Warfare Service after the war.

We recognize that the Engineer Corps constitute a small although brilliant and able branch of the U. S. Army, but they are not chemists. The matter might as well be vested in the Supreme Court, which also contains brilliant and able men, or even better in the Department of Agriculture, for competent chemists are to be found there. The Engineers cannot organize gas warfare when it is needed, because if anything has been proved by the war it is that it takes special practice among chemists to accomplish special results. We have heard manufacturers say, "Oh, we can hire chemists"—indicating that any man with a diploma could give them what they needed—for many years past until, as in England and France, the chemical side of our industries was neglected, and the Germans got the business. Chemical Warfare Service is a branch of the Army that cannot function save under constant practice.

We have given this matter careful consideration, and it is with neither heat nor emotion that we express our opinion that the War Department is seriously in error in the plan about to be adopted.

Western Chemical and Metallurgical Field

Notes on Metallurgical Activities in British Columbia

AN INVESTIGATION of ore-smelting charges in British Columbia, aimed particularly at the Trail smelters' schedules, has been dragging along for several months. After considerable agitation, a committee of four was appointed and held its first meeting at Nelson on Jan. 21, taking evidence from one mine owner in a closed session, then adjourning to meet later at Trail to discuss with the smelter officials the scope and ways and means of the investigation. Considerable objection has been voiced by mine owners to the present inquiry, and they have largely declined to co-operate with the committee, claiming that its personnel is unrepresentative and its powers so limited that no real benefit can result from its activities. Meantime the smelter management, having reduced smeltermen's wages 25c. per day, notified lead miners that the base rates effective April 15 would be reduced from \$8.30 to \$7.85 per ton.

The Consolidated Mining & Smelting Co.'s research department has been able to solve satisfactorily the metallurgical treatment of the complex lead-zinc ore from its Sullivan mine, an accomplishment of the utmost importance, making available an enormous tonnage of hitherto undesirable ores. Revision of the ore-dressing and metallurgical treatment in the zinc plant has already been started. On account of the added amount of blister copper to be refined which will result from the Canada Copper Corp.'s concentrates, the electrolytic refinery must also be enlarged to 50 tons daily capacity. A rod mill is also considered as a necessary adjunct in order to market this amount of copper in Canada.

Rapid progress in the new plant of the Canada Copper Corp. has been made. This company owns the Greenwood smelter, containing 3 blast-furnaces and 2 converters with a nominal capacity of 950,000 tons of ore per year. Operations have been spasmodic, however, blowing in for a short campaign whenever sufficient ore had accumulated. Thus but 2,200,000 lb. of copper was recovered in 1913, the plant finally shutting down when its principal ore supply, the Mother Lode mine, was exhausted. Since dismantlement of the smelter would be disastrous to the city of Greenwood and its environs, a citizens' committee has been endeavoring to raise the necessary funds to take over the plant and treat ores from the surrounding regions. The company has offered its plant to the committee at \$125,000, a very favorable figure in comparison to its value as a going concern; on the other hand, its sale would relieve the present owners of very considerable charges for taxes and insurance. All operations of the Canada Copper Corp. have therefore been removed to its Copper Mountain deposits, whose development is costing approximately \$2,500,000. About 12,000,000 tons of 1½ per cent ore has been blocked out, and a crushing plant and ore storage bin have been built at the mouth of the main haulage system. A 2000-ton concentrator is being built at Allenby, some 5 miles south of Princeton, and is expected to be in operation during the present summer. Its construction has been seriously delayed by non-completion of the 13-mile railroad connection to the

Canadian Pacific. During May the workmen employed by the grading contractor struck for an advance in pay, and work was not resumed for a month. Electricity will be had through a 103-mile extension of the West Kootenay Power & Light Co.'s lines, thus serving a consumer located 180 miles distant from the power house. Smelting and refining will be done at Trail.

Granby followed the lead of smelters in the States and posted notices of reduction of wages, following the drop in copper. Their employees at Grand Forks agreed to work for the Butte scale, effective March 1. However, the wage agreement was quite complicated, providing for a bonus of 50c. a day until wholesale prices of living necessities were reduced, a 10 per cent reduction on purchases made at the company store, and a decrease in charges for board. Employees at Anyox were not anxious to accept a reduction in wages, and during the parleys a fire burned a portion of the smelter building, causing \$50,000 damage and a shutdown for a month. Upon reopening, a considerable shortage of labor was experienced, but in time most of the vacancies were filled by returned soldiers. Since April 1, however, wages have been increased twice by the Granby company, and now are at about the same figure as at the beginning of the year.

British Columbia's first by-product coke plant was started at Anyox in June. Coal is furnished by Granby's own mines, near Nanaimo, and the resulting coke is consumed in its copper blast-furnaces. Tar is shipped to Vancouver, where a distillation plant separates the valuable fractions.

Company Reports

Jackling Porphyries.—The accompanying tabulation presents comparative milling data taken from the annual reports of the so-called Jackling Porphyries, viz.: Utah Copper Co., Nevada Consolidated Copper Co., Chino Copper Co. and Ray Consolidated Copper Co. Additional information as to operations and improvements are given below.

Utah Copper Co.—As is well known, this company operates two very large concentrators near Salt Lake City. A comparative statement of its tonnage is as follows:

	Magna	Arthur
Total tons concentrated.....	6,625,000	5,535,700
Daily treatment.....	18,151	15,166
Rated capacity.....	12,000	16,000
Extraction.....	57.9%	73.4%
Cost per ton, 1918.....	\$0.80	\$1.08
Cost per ton, 1917.....	\$0.62	\$0.78

Near the end of 1918 the new primary crushing plant at Arthur mill was put into operation. It includes a car dumper and electric haulage system, a very large crusher, a complete conveying system and two additional 72 x 20-in. rolls. This scheme overcomes all difficulties in handling frozen, wet, or very large blocks of ore. Similar work is under way at the Magna plant, which, with additions to the fine grinding plant and concentrating department, will double the rated capacity of the latter and materially increases its low extraction now due in part to serious overcrowding. As a matter of fact, the average recovery of both mills for 1918—65.1 per cent—is nearly a record and is especially noteworthy in comparison with the figure for 1917—61.1 per cent—which established a minimum.

The leaching plant above Magma operated throughout the year, handling little more than a third of its rated daily capacity of 3000 tons, owing to an inadequate precipitation and drying system. The ore treated is oxidized copping averaging 0.67 per cent copper soluble in dilute H_2SO_4 . Recovery amounted to 11.1 lb. per ton, of which only 10.6 lb. was precipitated and marketed in the form of cement copper, 48.8 per cent pure. Five pounds of 60 deg. B $\acute{e}$. acid was consumed per lb. of copper recovered. The cost of milling, leaching, precipitating, handling tailings and general expense at the leaching plant averaged \$1.06 per ton, or almost exactly 10c. per lb. of copper. Crediting an allowance for copper in stock solutions, and adding smelting and selling charges, Mr. Gemmell estimates the copper from the leaching plant as costing 15.1c. Apparently no charge is made for mining, since this ore overlays the sulphide ore and its mining cost is absorbed by the stripping charge. Supposing, however, that mining actually cost 45c. per ton, the cost of cement copper would be increased from 15.1c. to 19.3c. Apparently, then, the managing director's optimistic statements as to the leaching operations refer only to oxidized ore which is moved for stripping and which requires no further handling before delivery to the mill. This view is corroborated by the fact that the leaching plant was closed Jan. 1, 1919, the first department to experience curtailment.

Chino Copper Co.—Chino's recovery of 63.3 per cent was the lowest in its history, and reverses the record of 69.3 per cent made during the previous year. This is attributed to the necessity of mining ores containing undue percentages of oxidized copper, to a shortage of skilled labor and a failure in water supply. All alterations in the old mill were finished, and the new section 6 was started in February. Section 7 started in partial operation in July, but that portion devoted to treatment of oxidized ore was not operated, due to non-delivery of material. Actual milling costs increased 6 per cent over 1917. It may be noticed that the figure \$1.37 for milling cost per ton represents an increase of 33 per cent, but the balance represents the amounts reserved for taxes, which were not included in the earlier figures.

At Ray the extraction has shown a gradual increase for several years, which is the gratifying result of a series of minor improvements. The mill now has a capacity of 10,000 tons per day, the tube mill installation in the fine-grinding department having been put in operation in December, and the equipment of the slime plant expanded.

Nevada Consolidated mill recovery shows a decided drop over the record extraction in 1917, due to causes quite similar to those in effect at Chino. The actual tonnage handled should be increased 193,093 tons, this amount being custom ore received from the Consolidated Coppermines Co. This treatment of 11,650 tons daily is an increase of 20 per cent over pre-war years, and a series of minor alterations has now increased the capacity of mine, mill and smelter to about 13,000 tons per day.

The most important construction at the smelter was the installation of a 600-ton coal pulverizing plant for the reverberatory furnaces, replacing the scarce and expensive fuel oil. Four furnaces operated continuously, smelting 654,650 tons of charge, including about 43,000 tons of oxidized ores.

MILLING STATISTICS, PORTHARY COPPERS, 1918

	Utah	Chino	Ray	Nevada
Tons ore milled...	12,160,700	3,836,400	1,411,000	3,999,326
Copper content (per cent)	1.23	1.61	1.61	1.51
Pounds copper produced	188,092,405	75,655,641	81,599,160	76,607,062
Extraction (per cent)	65.11	61.3	74.9	67.1
Tons concentrate produced	16.1	278,413		
Copper content (per cent)	16.1	14.25	18.2	8.93
Milling cost per ton	\$0.93	\$1.37	\$1.01	\$0.93
Total cost copper per pound...	16.33c.	17.18c.	17.19c.	17.96c.
Extraction for 1917 (per cent)	61.1	69.3	74.5	73.1

Consolidated Mining & Smelting Co. of Canada, Ltd.—In the managing director's report for the year ended Sept. 30, 1918, attention is called to the fact that since the beginning of the war the company supplied the Imperial Ministry with the following major metals:

Electrolytic Zinc,	22,356 tons at 12 4/5¢ per lb.
Electrolytic Lead,	39,606 tons at 7 9/10¢ per lb.
Electrolytic Copper,	6,831 tons at 29 6/8¢ per lb.

All of these prices were materially below the average Canadian market price. Metallurgically, the smelting plant at Trail is in very good shape, and with a capacity not so far expanded as to flood the Dominion metal markets. The zinc plant especially has been thoroughly reorganized, and very large reductions made in costs. A new process for the complex ores of the Sullivan mine has been worked out by the research department, which is of the utmost importance, making available huge quantities of developed ore. While all the present plant will be utilized, considerable additions will be necessary to install the process on a 2000-ton scale, but when this is done there should be no trouble in producing zinc and lead at a profit on any market that has existed in recent years, provided the cost of labor and supplies falls with the price of these metals. Recently very material reductions in cost at the lead refinery have been effected, demonstrating that for small tonnage plants the Betts process can compare very favorably with the Parkes process. An arrangement has been made to treat the copper concentrates from the new mill of the Canada Copper Corp., which will involve an increase in the copper refinery from its present capacity of 20 tons per day to a minimum of 50 tons. A small rod mill also will be installed in order that this extra production may be marketed in Canada.

A. I. M. E. Plans Trip to Gary

In conjunction with a large technical program dealing with recent developments in iron and steel metallurgy, a trip to Gary has been planned for the Chicago meeting of the Institute. Arrangements are being made to charter a steamer to convey the members and guests across the south end of Lake Michigan, directly to the steel works. A tour will be made through the various departments of the steel plant, and luncheon will be served at Gary. Technical sessions on subjects in ferrous metallurgy will be held on the boat en route.

The banquet has been scheduled for the evening of Wednesday, Sept. 24, at the Congress Hotel. By putting this function in the middle of the week it is expected that a maximum attendance can be obtained; members able to come for only a portion of the session can then be present at the banquet, whether they come for the first or latter part of the week.

An elaborate program for the entertainment of the ladies is being prepared, and all members are urged to bring their wives to this meeting.

Andrew Carnegie

ANDREW CARNEGIE died of bronchial pneumonia at Shadow Brook, Lenox, Mass., Aug. 11, at the age of 84. His ancestors for generations back had been weavers. At the time of Andrew's birth, Nov. 25, 1835, his father, William Carnegie, owned a few hand looms. In 1848 the general adoption in Scotland of the steam loom forced William to take his wife and two boys, Andy and Tom, 13 and 6 years old respectively, to America. They made their first home in Barefoot Square, Slabtown, Pa., where the father found employment for himself as weaver and for Andy as a bobbin boy at \$1.20 per week wage. The mother sewed for a shoemaker named Phipps. Harry Phipps, the shoemaker's son, was three years younger than Andy. Through lifelong co-operation he and the Carnegie boys were to advance together from poverty to control of the steel industry.

Sixteen years of railroad work developed the big idea from which Mr. Carnegie was to reap his fortune. This was to replace wood construction with iron. On a visit to England in 1868, he learned of the bessemer process and soon had it working in his mills. His success in structural steel manufacture was masterful and he became principal owner of the Homestead and Edgar Thompson Steel Works and other large plants of the firms of Carnegie, Phipps & Co. and Carnegie Bros. & Co. Lake Superior ore and Connellsville coke were incidental developments. In 1899 the Carnegie Steel Co. dominated the steel industry, and in 1901 Mr. Carnegie, after thirty-seven years of activity in the field, retired with a fortune of \$460,000,000.

Mr. Carnegie's benefactions are in keeping with his wealth and are between 350 and 400 million dollars. Of this amount, 60 million was expended on 2811 free public library buildings; 20 million on colleges; 125 million on the Carnegie Corporation; 30 million on the Carnegie Foundation; 27 million on the Carnegie Institute of Technology; 22 million on the Carnegie Institution of Washington; 4 million on steel workers' pensions, 1½ million on the Engineering Societies Building of New York, etc.

Mr. Carnegie was the author of several books: "An American Four-in-Hand in Britain," 1883; "'Round the World," 1884; "Triumphant Democracy," 1886; "The Gospel of Wealth," 1900; "The Empire of Business," 1902; "The Life of James Watt," 1906; and "Problems of Today," 1909.

In 1888 he married Louise Whitfield. They had one child, Margaret, born in 1897. Miss Carnegie was recently married to Ensign Roswell Miller, U. S. N. The bridegroom was a sophomore in the civil engineering course at Stevens Institute, Hoboken, when war was declared. He planned at the time of the wedding to enter Princeton and complete his studies.

The epitaph to be inscribed on Mr. Carnegie's tombstone at the Sleepy Hollow Cemetery, Tarrytown, N. Y., was written by the steel master and is characteristically descriptive. It reads:

"Here lies a man who knew how to enlist in his service better men than himself."

Associates of Mr. Carnegie have paid elegant tributes to his memory, of which the following are typical:

Chauncey M. Depew—He had a talent beyond any of the constructive manufacturers and merchants, selecting with unerring sagacity the ablest men for the different departments of his industry. Having selected them, he not only gave them great liberties but also large wages according to their success, larger rewards than they could have secured elsewhere. He made many of them phenomenally rich.

Charles M. Schwab—It would be difficult for me to find words to express my love and admiration for Mr. Carnegie. He was my friend, partner and associate for thirty years. He was the greatest man I ever knew

and he had a heart so filled with tender sentiment, especially with reference to his associates, as to make him beloved as well as admired by all those who came in business or social contact with him. He possessed the faculty of inspiring others to unusual efforts in a greater measure than any man I ever knew, and he always won by expressions of appreciation rather than criticism. The world has lost a great man and a great benefactor to humanity, and I have lost a greater friend than whom no man ever had.

George W. Perkins, chairman of the finance committee of the Carnegie Foundation—I am deeply grieved to hear of Mr. Carnegie's death. He was a very great American, belonging to that class which after the Civil War was quick to appreciate that we had a united country and

great opportunity. He grasped the new machinery which inventors placed in our hands at that time, and with them threw all his great mental energy into developing our country. When his active business career closed, with the same energy he gave a large percentage of his wealth to movements that he believed would help the people. One of the last talks I had with him was about profit-sharing. He was most enthusiastic in his commendation of the Steel Corporation's profit-sharing plans, and expressed the belief that the principle of profit-sharing was destined to be a great factor in solving the problems between capital and labor.

James B. Clews—The death of Mr. Carnegie removes one of the greatest characters the world has ever known. In these days of labor unrest his career offers a fitting example of what can be accomplished by one commencing in the lowest station of life, when he possesses the necessary qualifications for rising in life and makes the most of his opportunities.

Carnegie was born a weaver, but he threaded together a tapestry of men instead of gilt and fiber.

ANDREW CARNEGIE

Army Reorganization Bill Discards Chemical Warfare Service

THE Army reorganization bill, as submitted to Congress, threatens the undermining of most of the technical development of the Army and does not even mention the highly technical Chemical Warfare Service. In a letter accompanying the bill, the Secretary of War suggests that the Chemical Warfare Service can be handled by the Engineer Corps. It is so apparent that this service is so entirely distinct from the work done by the Engineer Corps that chemists are aroused at what they believe to be unreasonable prejudice on the part of the professional element of the Army against a service which they feel contributed the most striking chapter to the record of the war. The General Staff's conception apparently is that a technical man is not fit to be an officer, or at least they intend to make a jack-of-all-trades of him.

Before officers can specialize on gas or any other technical development they must run the gamut of examinations and become thoroughly versed in all matters pertaining to the line of the Army. To make it still harder for the specialist, the bill provides that an officer may serve no more than four years out of any six in one line of duty.

GEN. MARCH AGAINST THE SERVICE

Congress has approved the Chemical Warfare Service to the extent of providing money for its continuance until June 30, 1920, but Gen. March has come out flatly against the service, although he does grant that research in gas should be continued. On the other hand, chemists point out that gas was used in the World War to a comparatively small extent. This was due partly to the lack of ingenuity and initiative on the part of the Germans and also to their lack of raw materials. When the war ended, however, such progress had been made by the Allied Governments as to make possible a fair idea of what might be expected in the use of gas in future wars.

It has developed since the armistice that Germany was so afraid of the possibilities of gas that she herself initiated a propaganda in December, 1917, looking to its being barred during the remainder of the war. In March, 1918, having learned that the Allies were making remarkable strides in gas production, Germany appealed openly for the suspension of gas warfare. That was after Germany learned that the United States alone was actually producing four times as much mustard gas as she herself could produce. As a matter of fact, ninety days after the armistice the United States would have been producing twenty times as much mustard gas as were the Germans, while our production of phosgene and lachrymatory gases were outstripping the German production in almost the same proportion.

OPPOSITION TO GAS WARFARE DIMINISHING

As gas warfare is better understood, the opposition to it is diminishing. Out of all gas casualties among the Allied armies, the death rate was less than 3 per cent. The death rate among casualties resulting from bullets and high explosives often runs as high as 25 per cent. That the Germans were greatly aided by their gas warfare, despite their clumsy use of a weapon that might have been wielded far more effectively, is shown by the fact that gas was responsible for three out of each ten casualties that they caused. An analysis of gas casual-

ties shows that very few of those injured were permanently disabled. There is concrete evidence that it is the most humane way of putting a man out of combat.

Study of chemical warfare leads to prediction by responsible persons that in a possible future war gas will cause 50 per cent or more of all casualties, but by certain changes in gases which even now are being developed the death rate will be cut to one-tenth of that among the casualties caused by high explosives. It is believed that the future will see any battlefield saturated with gas all the time, which will make necessary the continuous use of masks by all within the area.

The highly technical skill necessary in the carrying out of chemical warfare, as well as the need for immense industrial resources, gives the more highly civilized nations a weapon of tremendous efficiency. By the use of lachrymatory or similar gases, it might be possible to dominate a situation entirely without causing loss of life.

The basis of two-thirds of gases used in warfare is in coal-tar derivatives. Most of the remainder are chlorine compounds. An exception is the lachrymatory gas, which has a bromine base. Thus the United States is in an enviable position by having unlimited quantities of the needed raw materials and it is argued that it would be to the nation's advantage to have recourse to chemical warfare in case war became necessary.

The Microscope in War

Captain Howard I. Cole of the laboratory of Arthur D. Little, Inc., at Cambridge, Mass., told lately of the use of the microscope in war. Few persons are aware how large a part this instrument has come to play in chemical analysis, more particularly in the identification of materials.

The most important work was the analysis of defective explosives, primers and other munitions of the Allies, as well as the materials found in captured German shells and duds. By the micrometric measurement of powder grains, etc., it was often possible to report the efficiency of explosives, which is largely dependent upon the size of the particles.

A pocket case 8 in. long will carry as many as 60 little reagent tubes for microscopic work and, as can be readily understood, the chemist can operate with much smaller amounts of material with the microscope than he can without it. Indeed, if the problem has to do, for instance, with the nature of an enemy primer, the very small amount of material under the primer cap usually restricts analysis to this instrument.

Many bodies are determined by their crystalline forms, and both solids and liquids are often recognized by their refractive indices. Many poisons are identified by the same method. There are almost always a considerable number of suicides in battle, some from shooting and others from poisoning. The presence of the suspected poison in the stomach indicates the latter.

Many alloys are examined to discover their content, and the same may be said of fuses. Clothing of all sorts, balloon fabrics, paper cloth, captured sand bags and paper tape for carrying shells were examined to arrive at a sense of conditions in Germany. Food was under constant test to find out whether it had gone bad or not, or was adulterated.

The increased use of the microscope in progressive laboratories as compared with twenty years ago would surely surprise many an old timer.

British Government Aids Dye Trade

The British Board of Trade has set up a central importing agency which will be the sole medium through which dyestuffs can be imported into the United Kingdom. This agency will furthermore buy dyestuffs abroad on a commission of 1 per cent. The American Chamber of Commerce in London reviews the situation as follows:

On Feb. 24, 1919, the importation of all dyestuffs was prohibited except under license. At the same time the government, in accordance with its scheme for assisting the dye-making industry, set up a special Trade and Licensing Committee at Manchester in order to determine the kinds and quantities to be imported and to deal with all importing questions. To get immediate supplies with which to carry on, a general license was issued for all dyestuffs of bona fide American, French or Swiss origin, but this was withdrawn on April 9. Further, to regulate the import of dyestuffs and particularly to prevent the dumping of German materials on the British market, there has now been set up under the direct control of the Trade and Licensing Committee this Central Importing Agency through which all imports of dyestuffs must pass at some stage. This will include imports of German dyestuffs when such trade is allowed by the withdrawal of the trading with the enemy regulations.

Except in the case of German dyes, this Central Importing Agency will now undertake if desired the purchase of dyestuffs abroad on behalf of British consumers. Where it is desired, however, to make purchase direct or through recognized merchants, the goods will merely require to be consigned to the agency for the account of the particular consignee.

The Agency will charge a commission of 1 per cent on the invoice value of the goods for its buying services.

American Institute of Mining and Metallurgical Engineers

Mr. Charles M. Schwab will be a speaker at the banquet of the American Institute of Mining & Metallurgical Engineers to be held in Chicago Sept. 22 to 26 inclusive. Elaborate plans for both the technical and social side of the meeting have been perfected. Engineers who make the trip to Chicago for this meeting are assured of one of the most interesting annual meetings which the Institute has held. In addition to about one hundred and fifty papers which have been prepared for the meeting, trips to the zinc smelting districts, the steel works at Gary and the refineries at Whiting and East Chicago are included. A boat trip on the lake and numerous social events have been arranged for the ladies. The Fifth Annual Exposition of the Chemical Industries will be held in Chicago at the same time and members of the Institute are cordially invited to attend the exposition and become better acquainted with the allied industries.

Importations of German Potash Allowed

Besieged by the farmers on the one hand and the producers on the other, the War Trade Board section of the State Department had a busy time for a month prior to Aug. 7, when it finally decided to throw down the bars and allow the entrance of German potash. The producers now have placed their hope in Congress, and expect to obtain relief in the form of a tariff.

Sewage Disposal Committee

The Division of Chemistry and Chemical Technology of the National Research Council has formed a committee on sewage disposal composed of the following members: Prof. G. C. Whipple, of the Department of Sanitary Engineering, Harvard University, chairman; Major C. G. Hyde, professor of sanitary engineering, University of California; Lt.-Col. Edward Barton, professor of sanitary chemistry, University of Illinois; Lt.-Col. W. D. Bancroft; Prof. E. B. Phelps; Dr. W. W. Garner, physiologist, Bureau of Plant Industry, Department of Agriculture.

The committee will undertake the following projects:

1. To prepare a research survey of the field, with special reference to possible methods of sewage disposal which will recover the valuable oils, fats and fertilizer constituents of the sewage; this survey to include statistical data and a discussion of the economic aspects of the subject as well as the scientific ones.

2. To outline a series of basic research problems necessary to the further extension of our knowledge of the possibilities of recovering and utilizing the valuable constituents of sewage.

3. To ascertain what researches are already in progress in the country in connection with this problem and, if it seems desirable, to prepare a list of sewage experiment stations or similar organizations whose equipment and staffs may possibly be utilized in connection with any project of co-operative research which it seems wise to undertake.

4. To prepare general plans and estimates of cost of establishing a sewage experiment station to study new methods of treating sewage for the recovery of its valuable constituents and to work in close co-operation with investigators now engaged or who in the future may be interested in undertaking physical, chemical or biochemical investigations on various aspects of the problems which present themselves.

5. To investigate particularly the Rice process and the Miles process of sewage treatment and to make recommendations to the Division as to what action, if any, the Council might take with reference to research or development in connection with one or both of these processes.

British and American Dye and Chemical Traders to Send Commission Into Germany

The Dye and Chemical Trade Group of the American Chamber of Commerce in London is about to send a mission into Germany and Austria to study the commercial situation there as related to the dye and chemical industry. Present problems and future prospects will be studied, particularly with reference to import and export possibilities, methods of payment, necessary precautionary measures, etc. Both importers from America and British distributing merchants will be represented on this mission, and the information obtained will be put at the disposal of the industries in both countries. The State Department at Washington has been asked to give official recognition to the American delegates on this commission to enable them to proceed where they wish in Germany and Austria, and to accomplish the objects of their mission.

World's Gold Production

The production of gold has been steadily decreasing since 1915, when the highest point was reached. In that year the world's production of gold was \$468,724,918, of which the United States produced \$101,035,700, South Africa about \$188,000,000 and Australia about \$50,000,000. In 1918 the world's production was \$377,300,000, of which the United States produced \$68,493,500, South Africa \$176,000,000 and Australia \$26,700,000.

Experimental-Retort Tests of Orient Coal*

Description of Experimental Work for Coking Illinois Coal—Investigation on the Influence of Coking Temperature Upon the Quantity and Quality of Coke Produced—Comparison With Results Obtained When Using Other Coals

By R. S. MCBRIDE† and L. V. BRUMBAUGH‡

THE Bureau of Standards, in connection with two special coke-oven tests, found it desirable to investigate the influence of temperature of coking upon the quality of the coke produced and upon the quantity and quality of gas made from the coal. Although several very similar coals were used in the oven tests, the experimental-retort work was limited to coal obtained from the Orient mine of the Chicago, Wilmington & Franklin Coal Co., located at Orient, in the south central part of Franklin County, Illinois. The data obtained from the coking tests with this coal at various temperatures are of such general interest that they are presented here.

A series of five experimental-retort tests was made at various temperatures. The coking was done in a cylindrical retort of cast iron, set up as shown in Fig. 1. This apparatus was made available to the Bureau through the courtesy of the Bethlehem Steel Co., Sparrows Point, Md., which has used this equipment regularly for trying out coals or mixtures of coals intended for its by-product coke ovens. Data of a few similar retort tests on a variety of other coals which have been tested at this plant are presented for comparison.

APPARATUS AND METHOD USED

The cylindrical retort, shown in Fig. 1, was enclosed in a refractory-brick setting approximately 3 ft. in each dimension. It was heated by a large bunsen-type burner, using coke-oven gas. The sample of coal to be tested was pulverized and dried thoroughly, generally by allowing it to remain over night in an oven at approximately 100 deg. before introduction into the small cast-iron box used to hold the charge. The retort was heated up to a temperature from 60 to 100 deg. C. above the temperature desired for the test in order to allow for the unavoidable rapid cooling that takes place when the lid of the retort is opened for introduction of the charge. Immediately after each charge was placed in the retort an oil soaked rag was thrown in. This rag quickly took fire and exhausted the oxygen in the retort space, thus eliminating the possibility of an explosion as the gases from the coal were generated.

The temperature of the retort was maintained at the desired point according to the indications of thermocouple T_1 , the location of which is clearly shown in Fig. 1. Thermocouple T_2 furnished auxiliary temperature readings, but these were not used as the basis for temperature control. After introduction of the charge the lid was quickly closed and mudded up to prevent gas leakage. The gas driven off from the coal was discharged

from the retort through the outlet pipe shown in the figure. As soon as the gas from the coal began to appear at a purge cock in this line, this purge cock was closed and the gas allowed to flow into a small storage holder in which the entire volume generated from the charge was collected. During the test period record was taken at intervals of 5 min., showing temperatures of T_1 , T_2 , the volume of the gas collected in the holder, and the temperature of this gas. When the charge ceased gasing the coke was removed and quenched, and a record made of the barometric pressure and of the temperature and volume of the gas in the holder.

After quenching, the coke was examined thoroughly, a description recorded, and an average sample prepared

FIG. 1. EXPERIMENTAL RETORT

Arranged for heating by bunsen burner, using coal gas. Inside dimensions of retort: 9½ in. in diameter, 24 in. long; metal 1 in. thick. Inside dimensions of coal box: 9½ in. long, 4½ in. wide, 5 in. deep; metal ¾ in. thick. Space between outside of retort and masonry, 2½ in. Location of thermocouples: T_1 , 6½ in. from rear and 2 in. from top of retort; T_2 , 14 in. from rear and 4 in. from top of retort.

for analysis. The gas collected in the storage holder was analyzed, the candlepower and specific gravity determined, and the heating value calculated from the analysis. From these data were calculated the B.t.u. in the gas per lb. of coal carbonized, the cubic feet of gas per lb. of coal, and the candle-feet per pound.

COAL USED

The coal used for four of these tests was that remaining from the sample taken at St. Paul, Minn., when the Bureau tested the coke plant of the Minnesota By-Product Coke Co., using Orient, Ill., coal. For the fifth test there was another smaller sample remaining from

another shipment of Oregon coal used by the Bureau in a separate coke-oven test at Dover, Ohio. Table I gives the analysis of these coal samples as used in the retort tests. These analyses agree very closely with those of the carefully prepared samples analyzed by the Bureau of Mines in connection with the plant tests mentioned above. The results of these tests, therefore, can be regarded as typical of the results for the larger shipment. Table II shows the size of the coal as crushed for the retort test.

RESULTS OBTAINED

The results of the five retort tests are given in Table III. In considering these data it must be borne in mind that only a very limited number of tests could be made because of the small samples and the short time available for the work. One should be very careful, therefore, not to try to draw too many conclusions from these results.

TABLE I—ANALYSIS OF ORIENT COAL AS USED IN EXPERIMENTAL-RETORT TESTS (DRY BASIS)

	Sample from	
	St. Paul, Minn.	Dover, Ohio
Volatile matter.....	37.8%	38.0%
Fixed carbon.....	52.3%	53.4%
Ash.....	9.9%	8.6%
Sulphur.....	0.87%	1.47%
Phosphorus.....	0.007%	0.002%
Total carbon.....	73.0%	76.3%
Hydrogen.....	5.1%	5.3%
Oxygen.....	9.9%	8.5%
Ratio: Hydrogen-oxygen.....	51.6%	62.6%
B.t.u. per lb. (dry).....	12,800	13,000
B.t.u. per lb. (dry and ash-free).....	14,200	14,200

TABLE II—SIZES OF CRUSHED COAL AS USED IN EXPERIMENTAL-RETORT TEST

Mesh	Percentage Through Sieve
8	99.7
10	89.5
20	50.8
30	36.7
40	30.3
60	19.3
80	13.3
100	11.0

Test No. 1 was made as nearly as possible to duplicate the usual temperature conditions of testing followed by the Bethlehem Steel Co., so that a basis for comparison of this coal with others would be available. In this particular test the gas for heating the retort was cut off completely 40 min. after the introduction of the charge. The data from this test are the only ones which can be compared with the results given in Table IV for other coals. The coke from this sample was fairly good, and the charge was thoroughly coked, showing considerable contraction in the sample box. The pieces were the medium size with no evidence of sponge and only a small amount of fine pebbly material on top of the coke. The coke had very small and regular cell structure, but was soft, shattering rather easily, with a tendency for longitudinal fracture, but no distant cross-fracture. It was light in weight and of a dark silver color.

Test No. 2 was made at as nearly as possible constant vapor temperature (T_1) of 775 deg. C. This was approximately the average temperature of the vapor above the coal as recorded in the test of the coke plant of the Minnesota By-Product Coke Co., St. Paul, Minn., when the coking time was approximately 19 hr., but it is

probable that for the same temperature of retort as of oven the vapor temperature in the retort would be higher than the corresponding vapor temperature in the oven. The coke results obtained in this case should probably, therefore, be more nearly comparable with the results of special oven tests made at St. Paul when coking time was approximately 25 hr. The coke from this test was fair, contracted in the box and broke up into large

pieces with no sponge and only a small amount of fine material for about $\frac{1}{8}$ in. on the upper surface of the mass. It had small and slightly irregular cell structure; but as a whole the coke was clean, soft, and somewhat tougher than in test No. 1, with longitudinal fracture but no cross-fracture. It was slightly heavier than the material from test No. 1 and of dark color.

Test No. 3 was made with the idea of obtaining results at a somewhat lower vapor temperature above the coal than the average prevailing in the St. Paul test, but higher than noted in the other tests made by the Bureau at Dover, Ohio, where the vapor temperature above the coal averaged about 550 deg. C. It was attempted to maintain an average throughout for T_1 of 600 deg. C., and the results correspond very closely to this temperature. Judged by the results of this test, the coal would normally be characterized as only semi-coking at this temperature, for the coke was very poor. There was some contraction in the box and no sponge formed, but there was a very large amount of loose material, that appeared almost uncoked, on top of the larger pieces of coke. The cell structure was small and very irregular. Because there was a very poor cementing action, even the large pieces were soft and easily broken in the hand. The material was fairly heavy, with decided longitudinal fracture and no marked cross-fracture. The color was very dark.

For Test No. 4, in view of the very poor results judged by the character of the coke obtained in test No. 3, it was decided to conduct the test at a somewhat higher temperature. The effort was to maintain T_1 constant at 700 deg. C. throughout this test. Even at this temperature the coal would be characterized as semi-coking, although the coke was superior to that in

* These results refer to coke from full-size oven tests.

test No. 3. It showed contraction in the sample box, large pieces, and no sponge; but there was a large amount of loose and apparently uncoked material on top of the coke. The small and somewhat irregular cell structure, with soft friable material resulting from a poor bond, corresponds to what would be expected from the results of previous tests. The material was fairly heavy, with typical longitudinal fracture and no cross-fracture, indicating that at this temperature there was a decided tendency to secure blocky coke rather than that of a fingery shape. As in the previous test the material was very dark in color.

Test No. 5 was run with a small sample of coal remaining from the Dover test, in an effort to duplicate the conditions of test No. 3, namely an average for T_r of 600 deg. Although this coal came from an entirely different shipment from that used at St. Paul, the results were almost exactly the same as from the test No. 3, made at the same temperature.

By comparison of the results for the five tests, the very large influence of temperature of coking upon the quantity and quality of gas is evident. In Fig. 2 is

FIG. 2. RELATION OF GAS YIELD TO VAPOR TEMPERATURE T_r FROM EXPERIMENTAL RETORT TESTS
Test number is indicated beside each result plotted

shown graphically the change in quantity of gas per lb. of coal carbonized with changing temperature. In this connection it should be noted that the higher temperature results represent not only a more complete elimination of the volatile material from the coal, but also a decomposition of the heavier volatile material into the gaseous constituents. Naturally, as the vapors leaving the coal are subjected to this greater decomposition at higher temperature, the average heating value of the

FIG. 3. GAS GENERATED IN EXPERIMENTAL RETORT TESTS

gas is diminished. This diminution of heating value per cu.ft. is, however, by no means enough to offset the effect of the larger volume, as is shown by the fact that the B.t.u. in the gas per lb. of coal carbonized at 840 deg. is almost double that at 600 deg.

Fig. 3 shows the influence of temperature upon the rate at which the gas is generated and, of course, also the influence of temperature upon the time required for complete gasification of the charge.

INFLUENCE OF TEMPERATURE UPON CHARACTER OF COKE PRODUCED

As would be expected, the amount of volatile matter left in the coke decreases as the temperature of coking increases; and correspondingly with more volatile matter in the coke the yield of coke is higher. However, at the lower temperature the percentage of fine material

is much greater and the quality of coke very much inferior. In this connection, however, it should be noted that in none of the coking tests was it practicable to secure temperatures as high as are frequently used in oven practice with coals that are regarded as specially suited to the production of metallurgical coke. If such higher temperatures had been used another influence noted in connection with the St. Paul test would probably have appeared, namely, that at the high temperatures there is great tendency for the coke to be brittle, finery and small, instead of fairly tough and blocky.

As pointed out above, great care should be exercised in drawing the conclusions from these few tests. However these few conclusions are strong confirmation of

the results of the special oven tests made at St. Paul and are, therefore, a very valuable bit of supplementary data, which it is hoped will be of interest to the by-product coke-oven operators in general, but most especially to the operators who use Mid-Continent coals.

SIMILAR RESULTS ON OTHER COALS

For sake of comparison there are included in Table IV data for other coals similar to the data given in Table III for the Bureau's tests of Orient coal. A general comparison of these data is interesting, but no detailed conclusions should be drawn, as comparison of such single tests is apt to be misleading.

Washington, D. C.

Prices of Chemicals During the War

BY FREDERICK E. BREITHUT

Chairman, Chemicals Section, Price Section, War Industries Board

UNDER the direction of Dr. Wesley C. Mitchell, the Price Section of the War Industries Board has made an investigation of prices during the war. The results of this series of studies are embodied in some fifty-seven bulletins which are now in press. The aim of all these studies is to make the price quotations gathered by various Government agencies available to men concerned with problems of business readjustment, and also to provide a permanent record of the great revolution in prices that accompanied the World War.

The commodities selected for price study have been placed in five large groups as follows:

- Food
- Clothing
- Metals
- Building Materials
- Chemicals

Each of these groups has been further subdivided into classes of commodities industrially or chemically related, and a separate bulletin has been prepared for each class. The commodities placed in the chemicals group have been discussed in fourteen such bulletins issued under the following titles:

Number ¹	Subject	Author
1 (53)	Coal Tar Crudes, Intermediates and Dyes	W. N. Jones and F. W. Cassebeer
2 (54)	Drugs and Pharmaceuticals	W. Lee Lewis and F. W. Cassebeer
3 (50)	Essential Oils, Flavoring and Perfumery Materials	W. B. Meldrum
4 (56)	Explosives	C. L. Fry
5 (48)	Fertilizers	H. L. Trumbull
6 (46)	Heavy Chemicals	H. L. Lewenberg
7 (45)	Mineral Acids	H. L. Lewenberg
8 (47)	Miscellaneous Inorganic Chemicals	W. B. Meldrum
9 (57)	Miscellaneous Organic Chemicals	Arthur Minnick
10 (52)	Natural Dyestuffs and Tanning Chemicals	P. W. Carleton
11 (44)	Paints and Varnishes	Arthur Minnick
12 (55)	Proprietary Preparations	W. Lee Lewis and F. W. Cassebeer
13 (49)	Soaps and Glycerine	H. L. Trumbull
14 (51)	Wood Distillation Products and Naval Stores	P. W. Carleton

To throw as much light as possible upon the course

¹The serial number of each bulletin is given in parentheses.

of price fluctuations, each bulletin includes a brief résumé of conditions prevailing in the industry of which it treats, and discussion of data regarding production, imports, exports, stocks, Government purchases and Government control. Special emphasis has been placed upon the factors influencing the markets and causing marked variations in prices.

PRICE CHARTS TO SHOW MOVEMENT AWAY FROM PRE-WAR LEVEL

All the bulletins contain graphic representations of the price fluctuations of commodities. These price charts are primarily designed to show the movement of prices away from the pre-war level. They are drawn on a uniform scale and hence are strictly comparable with one another. The average actual prices in the 12 months preceding the outbreak of the war, July, 1913, to June, 1914, inclusive, have been taken as equal to 100, and the actual prices in the whole 72 months

CHART I.

from January, 1913, to December, 1918, inclusive, have been converted into relative prices on this basis. If, for example, the selling price of bromine averaged 30c. per lb. during the 12 months preceding the outbreak of the war, and if it rose to 40c. per lb. in December, 1914, the relative price in that month would be 133; if the price rose to 75c. per lb. in September, 1918, the relative price for the latter month would be 250.

For the benefit of those who wish to gain some idea of the general trend of prices in an industry in addition

to the fluctuations in prices of particular commodities, "index numbers" have been calculated. The simple average of the prices of the commodities sold—some by the gram, some by the ton, some by the gallon and some by the liter—would obviously have little value. Therefore, in making index numbers each commodity has been "weighted" by multiplying the monthly prices from 1913 to 1918 by the amount of the commodity produced in 1917, combined with the imports of the commodity during the calendar year 1917. That year was selected as the weighting year because the tables are intended to reflect war-time conditions, and because production data for 1918 were not obtainable for many commodities when the bulletins were being written.

HOW "INDEX NUMBERS" WERE OBTAINED

An enumeration of the successive steps in making these index numbers will show more clearly the significance of the figures. First, for every commodity included in the computation there was made an estimate of the total quantity produced in the United States in 1917, and to this amount the amount imported in the calendar year 1917 was added. The sum represented the "commodity weight." Second, the commodity weight was multiplied by the price of the commodity in each month of the six-year period covered. The product in each case was the "weighted price" for the month. Third, the weighted prices for all the commodities in the class dealt with were added up for each month. This gave the "monthly aggregates" for the class. Fourth, the average monthly aggregate for the 12 months ended June, 1914, was computed. Finally, the average monthly aggregate for the 12 months ended June, 1914, was made equal to 100, and the monthly aggregates for the 72 months changed into relatives on this basis. The results are the index numbers of the class.

The index numbers derived in this way for an industry are strictly comparable with the relative prices for particular commodities. By making use of them one can get a clear idea of average price fluctuations in a given branch of business and can compare fluctuation in one industry with those in others.

In addition to the 50 bulletins devoted to separate classes, the series of price studies includes group bulletins on the prices of foods, metals, clothing, building materials and chemicals. There is also a set of international comparisons of price fluctuations, a special record of Government control over prices during the war, and, finally, a general summary of the whole inquiry, in which the methods employed are set forth more fully and in which the leading results from all the bulletins are drawn together for comparison.

It is the purpose of this paper to summarize the results shown by the 14 class bulletins and the group bulletins dealing with chemicals. To this end two charts have been prepared.

CHEMICALS COMPARED WITH ALL COMMODITIES

Chart I shows the index numbers of chemicals as compared with "all commodities." Comparative features of the two curves are so outstanding that they call for little comment. The "all commodities" curve does not begin its rise until the middle of 1915 and except for a slight depression in the middle of 1916 continues its steady upward course to the neighborhood of 200. The curve for chemicals, on the other hand, begins

its rise in the middle of 1914, showing immediate response to the outbreak of the war in Europe. The steep rise in price mounts until reaches almost 200 in the spring of 1916. By this time the United States and the Allies had got into large-scale production, and as a consequence there is a depression, which lasts until the beginning of 1917. The entrance of the United States into the war is immediately followed by a sharp

rise in prices of chemicals until the old high level of about 190 is reached. The signing of the armistice finds the price of chemicals hovering in this region. With the signing of the armistice, however, there is a marked contrast between the behavior of the prices of "all commodities" and the behavior of the prices of chemicals. The upward trend of the prices of "all commodities" continues, but the prices of chemicals show instant depression. The tremendous stocks of chemicals on hand and the new facilities and equipment

for production—far beyond our needs in normal times—cause this drop.

PRICE FLUCTUATIONS OF CHEMICALS

Chart II presents an analysis of the curve representing the price fluctuations of chemicals. The thin lines represent the index numbers of the 14 classes of chemicals. The heavy line represents the "weighted" index numbers of all chemicals. If we look upon the pre-war base as an elastic band, seeking its normal place at the 100 line, and imagine the play of economic forces as pushing and pulling this band above or below the pre-war level, we have a vivid picture of what actually took place. If we add to this interpretation that the effects of these pushings and pullings on the elastic band shall be proportionate to the "weights" of the industries as represented by the volume of business, we then have a full picture of what this chart attempts to show.

It will be observed that the index numbers of class I (coal tar crudes, intermediates and dyes) showed such extreme variation during the period April, 1915, to September, 1916, that they cannot be represented on the scale as drawn in the chart. Therefore the actual figures for this class are given in Table I.

TABLE I—COAL TAR CRUDES, INTERMEDIATES AND DYES

Index Numbers by Months, 1913-1918
Base, Average Price July, 1913, to June, 1914—100

It is difficult to avoid entering into a detailed discussion of each of the classes, but all these matters are fully covered in individual bulletins, and this paper has for its sole purpose the presentation of a rough, general survey of the whole field. The general economic conditions incident to the war played their several parts. The blockade of German ports, the withdrawal of maritime commerce, the congestion of shipping terminal facilities, the destruction of ships and cargoes, high insurance and shipping rates, the diversion of labor to military ends, Government restrictions and purchases, increased war demands for explosives, drugs and many other chemicals—all found their reflection in the price fluctuations.

SHOULD LEAD TO VALUABLE SUGGESTIONS AS TO FUTURE OF AMERICAN CHEMICAL INDUSTRY

Finally, it may be stated that a careful consideration of these bulletins should lead to valuable suggestions regarding the future of American chemical industry. Wherein are we chemically independent? In what fields are we handicapped? What are the economic principles which should guide our legislators? Will capital take up the development of our chemical industries with the same thoroughness it has shown in other fields? What are the best measures to insure the permanence of an American dye industry? Numberless questions press for solution. To act intelligently we need, first and foremost, the facts. These bulletins make available the needed information on prices.

Oil Shales

BY LOUIS SIMPSON

OWING to the continued steady increase in the consumption of hydro-carbon oils and the probable exhaustion of the world's oil fields at a date not very far distant, and because of the probable early exhaustion of certain of the fields as are most conveniently located, it has become necessary to seek for supplies of oil from other sources. No source at present known offers such possibilities as those of the oil-yielding shales and associated deposits containing oil found in nearly all parts of the world.

One quality of such shales has for over 50 years been mined and retorted in Scotland. The retorts used today in that country have been perfected to retort the special quality of shale mined, and take into consideration the very special conditions, industrial, commercial, financial and climatic, existing in Scotland.

As the cost of constructing the retort plant and the cost of operating are vital factors in the commercial operating of such plants, it was natural that engineers and others should devote time to the construction of retort plants that would retort the quality of shale found in countries other than Scotland at less cost, or with a larger yield of oil or a yield of oil of a more desirable quality. This is especially true since the Scotch retort, when erected outside of Scotland, has generally proved to be a failure.

For some reason not apparent, it has been usual for those who have reported or written upon the oil shales question to recommend the use of the Scotch retort and practice and the employment of Scotch engineers, even when they had no experience other than that they had gained in Scotland, and this in the face of the fact that the works erected outside Scotland and which have proved to be failures have chiefly been operated by Scotch officials.

SCOTCH RETORT METHODS NOT APPLICABLE EVERYWHERE

The object of this article is to explain why Scotch retort methods and experience should no longer be considered the last thing in oil shale retorting and why it is necessary that an open mind should be kept when seeking for the best method of retorting a known deposit of shale.

The differences in local conditions are so extreme and are of such character that the blind adoption of any retort should be precluded, even though the retort has been used for years under certain local conditions, as in the case of the use of Scotch retorts by Scotch operators. These differences are found not only in the quality of shale to be retorted, which varies not only as to the extent and character of volatile contents but also as to the extent of nitrogen and carbon contents (the character of the shale itself also varies), as well as in the conditions under which the shale is to be retorted.

It must be evident to every thinking man that a retort may work well when retorting shale that contains, say, 25 gal. of crude oil to the ton and yet may not work satisfactorily when retorting a shale that contains 50, 60 or even more gallons to the ton. Also it is evident that a retort that will operate satisfactorily when retorting shale that contains only 2 to 4 per cent carbon may not be an economic apparatus when retorting shale that contains between 20 and 30 per cent carbon.

It should require no argument to prove that a retort that may be an economic means of recovering the contained nitrogen from shale and that will give a yield of 50 to 75 lb. of sulphate of ammonia to the ton shale might cease to be an economic apparatus when operating on shale that will yield only from 20 to 30 lb. of sulphate of ammonia.

VARYING LOCAL CONDITIONS SHOULD BE CONSIDERED

The quality of shale and of the associated deposits found throughout the world varies within very wide limits, as is above indicated, but the local industrial, commercial, financial and climatic conditions vary as greatly. It is not safe to assume that any new idea, because it is different from those adopted in Scotland by the Scotch oil shale operators, is worthless or that it is not worthy of adoption.

Up to date, there is only one commercial method by which oil is recovered from oil-yielding shale, but there have always been many different applications of the principles that govern the method, and the future will probably see nearly as many different applications as there are different qualities of shales. This method consists of the exposure of shale (placed in a closed chamber to which an exhauster is connected) *to the action of heat*, afterward condensing and working the gases so educed.

Other methods of extraction have been considered, but up to date none has warranted commercial demonstration, but it does not follow that in the future there may not be discovered a method which, by extracting the oil contents from shale that for diverse reasons cannot be retorted, may become of commercial interest.

The retorts now used in Scotland have been in operation about 20 years, and more than one make of retort is being used. It is not unusual to be told in reports that "the Scotch retort has been in use for over 50 years," which, of course, is a gross misstatement.

VARIATIONS IN METHODS OF RETORTING

All the retorts that up to date have been used commercially employ the same principle, the differences being only in the methods of application used. The variations occur in the methods employed:

1. To place the shale within the retort.
2. To remove the spent shale.
3. To apply the required heat.
4. To produce the required heat.
5. To conserve the heat.
6. To remove the educed gases.
7. To condense the educed gases.
8. To wash the gases that resist condensation.

In every commercial proposition the secret of ultimate success will be found in the most economical application of material and appliances suitable for the work, which, perhaps, have been in use in other industries (although unknown to the Scotch operators) or which have recently been discovered.

The question of whether the nitrogen contents of this shale should be fully recovered or otherwise is not argued here. That is a financial and commercial problem requiring an article to itself, but it is well to remember the industrial axioms:

1. That it seldom pays to seek to recover the last percentage.
2. That, with few exceptions, it is not wise to try to save by-products unless the profits received from such recovery equal or exceed the profits that would accrue from the investment in the original business of the money expended in the recovery.

Of the variations in the application of the methods above noted the following may be said:

1. The raw shale may be fed green or dried and may be fed intermittently, that is, the shale may be charged, then educed, and after education be discharged, or it may be fed semi-intermittently, as is done in the Scotch retorts, where a batch of shale is dumped into the retort every so many hours, but without any break in the work of education, or it may be fed continuously, as in the Del Monte and some other retorts.

2. The spent shale may be removed intermittently or continuously.

3. The heat may be supplied from combustion chambers surrounding the retorts, the heat in such case having to pass through the walls of the retort, or it may be furnished by the admission of preheated fixed gases into the retort.

4. The required heat may be produced by the use of methods too numerous to mention, the best method being that which consumes the least fuel and calls for the fewest repairs.

5. The art of conserving the heat units supplied to the retort has been much neglected in Scotch practice.

6. The removal of the educed gases may be provided for in different ways, but that used by the Scotch is one of the least scientific or desirable, and was only adopted because the method used in Scotland to recover the nitrogen content of the shale necessitated the use of large quantities of steam within the retort. But for this use of steam for another purpose, it would never have been used to assist in the removal of the educed gases.

7. The condensation arrangements, as used in Scotland, are not satisfactory, even under the conditions that exist in Scotland, and are impossible under climatic conditions known to exist in certain districts of the North American continent. The Scotch use atmospheric condensation. The variations experienced in the temperature of the atmosphere in Scotland rarely exceed 60 deg. F., and yet sometimes trouble is experienced. Since temperature variations in parts of this country exceed 120 deg. F. and even 150 deg. F., the use of atmospheric condensers here would be an impossibility. To obtain the best results the work of condensation must progress at the same rate under varying weather conditions.

8. Washing the fixed gases for the recovery of naphtha is a minor question, but one that should not be ignored. In this, again, Scotch practice is not the best, even though Scotch machine builders are producing one of the best mechanical washers known.

It probably is not possible so to design a retort plant that it will contain all the most desirable applications, and the most desirable ones only, but the retort of the future must at least possess a large majority of the most desirable applications, and must also be capable of being quickly constructed, and at a cost very much lower than the present cost of the Scotch retorts.

CONCLUSIONS AS TO MOST DESIRABLE PRACTICE

Of the several variations in the applications noted, the most desirable will certainly be found to be:

1. Continuous feed of dried shale.
2. Continuous removal of the spent shale.
3. Heat supplied through the medium of a preheated gas.
4. A method by which this heat can be supplied without subjecting the retort proper to the high temperatures used in the Scotch retort.
5. Where all heat is conserved to the fullest extent.
6. Where the educed gases are removed as soon as they are educed.
7. Where the educed gases are condensed, under conditions that permit of condensation at a constant and regular speed, and where the resultant oils are delivered fractionated into oils of four or more densities.
8. Where the washer, without long stoppages for cleaning or repairs, will clear the forced gases of all naphtha.

It is also very necessary that the plant should be so laid out that the ground covered is reduced to a minimum. This is necessary not only to reduce the

cutlay upon pipes of all sorts, but also that the building (which should be of fire-resisting construction) may not be too costly. It is possible so to arrange that a plant with a capacity of 1000 tons of shale in 24 hours, including shale crusher, boiler and power house, but not including storage tanks, will not cover more ground than 2500 sq.ft.

Arrangements should be provided for the economical production of electric power in quantity sufficient to supply the requirements of the plant, including the mines and the transportation system, and also provide the works and the workmen's houses with electric light.

The question of the commercial recovery of the nitrogen in the shale will be considered in another article.

Oil Shale Industry

Owing to the increasing demand for information on oil shale, the Bureau of Mines has recently issued a short paper giving a general discussion of the subject, together with a comprehensive list of references, covering all the important articles published in the United States and Scotland, as well as numerous articles published in other countries.

The paper reviews the history of the oil shale industry in Scotland; presents the status of the industry in the United States; compares conditions in Scotland with those in this country and draws a comparison between the petroleum industry and the oil shale industry, since the former is firmly established in this country and the principal products to be obtained from oil shale are closely related to those obtained from petroleum. Economic features in the development of the industry are also brought out and discussed.

The paper also contains directions for testing shale for oil and ammonia yields, prepared by E. M. Bailey, chief chemist of the Pumphreton Oil Co., the largest producer of shale oil products in Scotland, and describes the methods in use by the United States Geological Survey for assaying shales.

Copies of this paper, the title of which is: "Notes on the Oil Shale Industry, With Particular Reference to the Rocky Mountain District," may be obtained by addressing the Bureau of Mines, Washington, D. C., or the Bureau of Mines Experiment Station, Salt Lake City, Utah.

Senate to Act on Water-Power Bill

There is a movement on foot among the members of the Senate to pass the water-power bill without respect to the difficulties which surround the present discussion concerning the League of Nations and other foreign relations matters and without respect to the inquiries which are now being suggested concerning the high cost of living and the demands of the railroad employees.

It is expected, among Senate leaders, that the water-power bill, which is known as House of Representatives resolution No. 3184, will be reported out by the Senate sub-committee, of which Senator Jones of Washington is the chairman, within a few days. Senator Jones has not yet returned to his work in the Senate from his visit to Seattle, but he is momentarily expected in Washington, and the best information obtainable concerning the water-power bill, according to the Washington report of the McGraw-Hill engineering publications, is that immediately upon his return action will be had upon the bill.

Flotation Monopoly in Spain

IT IS reported that Minerals Separation, Ltd., of London has made a contract with the Sociedad Minera y Metallurgica de Penarroya whereby the latter becomes the sole owner of Minerals Separation flotation patents in Spain. A new company has been organized for the development of the flotation business and it is understood that Minerals Separation has taken an interest in the new company as part compensation for the rights assigned. For the present, it is reported that the Penarroya company will retain the flotation process for its exclusive use, although licenses may be extended to others on terms which have not been announced.

The Penarroya company is said to be practically in control of the lead industry of Spain, owning or controlling every lead smelter in the country. Lead-ore producers are practically at the mercy of the Penarroya company, since ore cannot be shipped out of the country owing to the distance of most of the mines from the sea. As a consequence of this domination the attitude of lead-ore producers is antagonistic to the smelting monopoly. The acquisition of the flotation patents enables the Penarroya company to control the production of lead not only from ore but from concentrates as well, at least for the life of the flotation patents. This latter is of considerable importance when it is realized that the quantity of low-grade ores in Spain is far in excess of that available for direct smelting. In addition to the large deposits of low-grade ore there are enormous dumps in many districts which could be economically treated by the flotation process. The Penarroya company possesses a further advantage in maintaining this monopoly by reason of its association with the banking house of Bauer, which owns the railroads covering the great mineral district tributary to the Penarroya smelters, of which there is one in Linares, and two at Cartagena. This offers superior facilities for the movement of ore, coal and coke, all of which the company owns and produces. The smelter at Linares is owned by the Penarroya company, while the two at Cartagena are controlled by contract. As reported in this journal some months ago, a new smelter is to be erected at Penarroya by Bradley, Bruff & LaBarthe, San Francisco engineers. It is expected that this smelter will be ready for operation early in 1921.

At the fourteenth ordinary general meeting of Minerals Separation, Ltd., held July 3, the chairman, Mr. Francis L. Gibbs, said:

The large business which lies before us in Spain, which, as you are aware, we are commencing with the assistance of the Sociedad Minera y Metallurgica de Penarroya, has required considerable organization, and for this purpose we are fortunate in having been able again to secure the services of Lieut.-Col. A. C. Howard, D.S.O., M.C., of our engineering staff, who has served with much distinction throughout the war and who has been appointed our resident chief engineer in Spain. With a staff of our engineers, Colonel Howard is actively engaged in bringing to the notice of mine-owners in Spain the great advantage to be gained by the adoption of our methods of concentration. One of the most important matters upon which Colonel Howard and his staff will be engaged during the next few months is the investigation by means of drills of a very large copper concession over which we, in conjunction with the Penarroya company and other powerful groups, have acquired an option. Captain Broadbridge, our chief engineer, examined this concession, and both he and the Penarroya company's engineer report the existence of immense quantities of low-grade copper ore, which can be successfully treated by our processes. Development of this concession is being energetically pushed.

Relation of Microstructure to Phase Changes in Heat-Treated Aluminum Bronzes

Description of the Influence of Heat Treatment on the Microstructure and Other Physical Properties of a Cu-Al Bronze of the Composition 90 Per Cent Copper and 10 Per Cent Aluminum
—Adaptability of This Bronze for Bearing and Corrosion-Resistant Metal

By L. R. SEIDELL* AND G. J. HORVITZ†

OF THE aluminum bronzes ranging in aluminum content from 9 to 15 per cent, the most important commercially has the composition 90 per cent Cu and 10 per cent Al. This bronze when subjected to heat treatment exhibits interesting variation in microstructure and other physical properties. Previous investigation has demonstrated that with slight variations in the aluminum content above or below this composition wide variations in physical properties of treated and untreated bronze are also obtained.

Our tests, however, were confined to the alloy having the composition 90 per cent Cu and 10 per cent Al, and were carried out as follows:

1. Differential heating and cooling curves were obtained.
2. Specimens were quenched in water at intervals of 100 deg. F. from 800 to 1800 deg. F. and brinelled.
3. Specimens quenched at 1600 deg. F. were drawn at temperatures ranging from 700 to 1500 deg. F. and brinelled.

FIG. 1. THERMAL DIFFERENTIAL CURVES AND CONSTITUTIONAL DIAGRAM

4. Microstructure of representative heat-treated specimens was studied.

THERMAL DIFFERENTIAL CURVES

On heating, the first phase change occurs at 1030 deg. F. and is due to transformation of $\alpha + \beta$ to $\alpha + \gamma$, all of which are solid solutions. The next change takes place at 1550 deg. F. This is much less pronounced than the first and represents the point at which absorp-

FIG. 2. EQUILIBRIUM DIAGRAM

tion of the α into β solid solution is complete. Upon reaching 1895 deg. F. liquation sets in with a consequent large absorption of heat.

On cooling, the point at which α begins to separate from β agrees closely with the corresponding point on heating. However, there is a lag of about 50 deg. F. at the β to γ phase change.

FIG. 3. BRINELL HARDNESS, QUENCHING TEMPERATURE

The constitutional diagram shown beside the heat curves in Fig. 1 represents the nature of the physical constituents present in the different ranges. Below 1030 deg. F. about 17 per cent γ and the remainder α

*Managing Director, New York Testing Laboratories.
†Metallurgist, New York Testing Laboratories.

FIG. 4. BRINELL HARDNESS, DRAW CURVE

are present. Above 1030 deg. F. areas formerly γ solid solution are now β . As the temperature rises above this point, α solid solution is absorbed into the β until 1560 deg. F. is reached, at which absorption is complete and structure is 100 per cent β . By quenching from any temperature after holding for a sufficient length of time to insure equilibrium, the nature of the constituents will correspond to those indicated in the diagram for that particular temperature. The phase changes of the thermal curves coincide closely with those of the equilibrium diagram of this particular alloy.

This diagram, first worked out by Curry in 1907, and as generally accepted in the form illustrated in Fig. 2, shows α which is soft and ductile up to 9 per cent

FIGS. 5 TO 13

Fig. 5—Brinell 112; 1100 deg. quench; $\times 100$. Fig. 6—Brinell 133; 1300 deg. quench; $\times 100$. Fig. 7—Brinell 163; 1400 deg. quench; $\times 100$. Fig. 8—Brinell 205; 1500 deg. quench; $\times 100$. Fig. 9—Brinell 240; 1600 deg. quench; $\times 100$. Fig. 10—Brinell 200; 1800 deg. quench; $\times 100$. Fig. 11—Brinell 118; as cast; $\times 50$. Fig. 12—Brinell 140; 1600 deg. quench, 1000 deg. draw; $\times 100$. Fig. 13—Brinell 98; annealed at 1600 deg.; $\times 200$.

and $\alpha + \gamma$ from 9 to 15 per cent aluminum. β ranges from 10 to 15 per cent, with eutectoid point at 12.5 per cent and 1051 deg. F. β has greater tensile strength than either α or γ with correspondingly low ductility.

A series of specimens $\frac{1}{2}$ in. thick were cut from a bar $1\frac{1}{2}$ in. in diameter. These were quenched in water at temperatures ranging from 800 to 1800 deg. F. Brinell hardness tests were made on each sample and a curve of results plotted (Fig. 3).

Specimen No.	Treatment	Brinell (1000 kg.)
1	As cast	118
2	800	121
3	1000	126
4	1100	112
5	1200	121
6	1300	133
7	1400	163
8	1500	203
9	1600	240
10	1700	240
11	1800	200

The hardness curve follows the phase changes closely and is maximum when the alloy is in the β condition.

To determine the effects of tempering on quenched samples, another series of specimens were water-quenched at 1600 deg. F. and drawn at temperatures from 700 to 1500 deg. F. A curve (Fig. 4) plotted from results of Brinell hardness test showed little drop in hardness up to 700 deg. F. Between 700 and 900 deg., however, maximum drop in hardness occurred. From 1100 to 1500 deg. there was little change.

Specimen No.	Water-Quenched at 1600 Deg. F. and Drawn at	Brinell (at 1000 kg.)
1	700	230
2	800	178
3	900	157
4	1000	140
5	1100	133
6	1200	125
7	1300	115
8	1400	110
9	1500	108

The following are indicative of physical properties of this alloy as cast and heat-treated:

Treatment	Elastic Limit Lb. Sq. In.	Ultimate Strength Lb. Sq. In.	Elongation per Cent
As cast	15,000	60,000	28.5
*W. Q. 1470	31,000	98,000	8.0
*W. Q. 1650	55,000	95,000	3.5
*W. Q. 1650 (drawn at 930 deg. F.)	49,000	86,000	12.0
*W. Q. 1650 (drawn at 1300 deg. F.)	41,000	80,000	22.7

That heat treatment greatly improves the strength of this bronze is borne out by the above figures.

MICROSTRUCTURE

The structure represented in Fig. 5 is that of a specimen quenched at 1100 deg. F. The solid solutions α and β are present, the α crystals showing considerable twinning. Figures 6, 7 and 8, of specimens quenched at 1300, 1400 and 1500 deg. F., respectively, show progressively smaller α crystals as the quenching temperature rises. This is due to absorption of γ into β as stated above. Quenching at 1600 deg. F. results in practically all β (Fig. 9), while still higher temperatures merely increase grain size and impart a striated structure to the crystals as indicated in Fig. 10.

A comparison between the structure of the bar as cast and after heat treatment explains in part the cause of considerably greater tensile strength in the case of the treated bronze. The former shows massive primary crystallization of α and γ (Fig. 11) and the latter, quenched at 1600 deg. F. and drawn at 1000 deg. F., a close-grained mixture of needle-shaped α crystals in a matrix of β (Fig. 12). Prolonged annealing at 1600 deg. F. results in α and eutectoid of α and γ (Fig. 13).

The foregoing results suggest the advisability of investigating this alloy for use as a bearing metal. In this connection a structure such as that shown in Fig. 8 may be found desirable. This alloy also may be substituted for steel parts, where special qualities, such as resistance to corrosion, are desired, since in the heat-treated condition its strength compares favorably with that of steel.

Electrical Conductivity and Other Properties of Saturated Solutions of Copper Sulphate in the Presence of Sulphuric Acid

By H. M. GOODWIN AND W. G. HORSCH

THIS paper gives the specific electrical conductance at 25 deg. C. of solutions saturated with copper sulphate and containing sulphuric acid ranging in concentration from 0.15 equivalent to 3.6 equivalents per liter. The solubility of copper sulphate in the presence of the sulphuric acid and the specific gravity of these solutions are also given. It was intended originally to extend the measurements over a range of temperatures, but circumstances having thus far prevented, it is thought desirable to publish and make available the results already obtained. The calculation of the conductivity of such concentrated mixtures is, in the present state of our knowledge of the degree of ionization of the salt and acid in the presence of each other, practically impossible if accurate results are desired.

The solutions used for these measurements were prepared in wide-mouthed, glass-stoppered bottles of 250 cc. capacity by adding to 200 cc. distilled water an excess of copper sulphate crystals and the desired (approximate) amount of 95 per cent sulphuric acid. Chemically pure sulphuric acid and copper sulphate from a well-known manufacturer were used. The copper sulphate was further purified by two crystallizations. Each bottle was rotated for 2 hr. in a constant temperature bath held to within ± 0.02 deg. of 25 deg. C. At the end of this time the conductivity of the solution was measured without removing the solution from the bottle or the latter from the thermostat. It was then rotated for an hour longer and the conductivity again measured. This procedure was continued until the conductivity became constant, which constancy was taken as the criterion for saturation having been reached.

The customary Wheatstone bridge arrangement with a slidewire of the drum type was employed in making the conductivity measurements. A generator furnishing sine wave alternating current at a frequency of 300 cycles per second served as the source of current. The conductivity cell was formed by introducing a pair of plunge electrodes, held rigidly with respect to each other, directly into the wide-mouthed bottle in which the solution was rotated. Each electrode consisted of a cylinder of platinized platinum held about 2 cm. from the lower end of a glass tube of about 1 cm. inside diameter. Be-

low the electrodes the tube was drawn down to 0.5 cm. inside diameter for a distance of 1.5 cm. The bulk of the resistance occurred within these projecting tubes, and the "cell constant" was independent of a reasonable amount of displacement from the normal location of the electrodes in the bottle.

The cell constant was determined by measuring the conductivity of a sulphuric acid solution of maximum conductivity and of a normal potassium chloride solution. The average of the two methods of calibration was used in computing the results, the percentage deviation of the

mean cell constant being less than 0.25 per cent. The precision of the final conductivity results is about 0.5 per cent.

The density of the solutions was determined to ± 0.1 per cent by means of a Mohr-Westphal balance. The results are given as specific gravity referred to water at 4 deg. C.

The copper sulphate content of the solutions was determined by electro-analysis, using, in some cases, a platinum dish as cathode and a rotating platinum anode, and in others a rotating platinum cathode which consisted of a 100 cc. platinum crucible suitably mounted. It was hoped at first that the acid content of the original

solution might be obtained by titrating for total acid after the removal of the copper and subtracting the acid equivalent to the amount of copper deposited. Test experiments showed this method to be inaccurate, however, by from 1 to 2 per cent, due largely, probably, to secondary reactions occurring during the electrolysis.

The method was therefore abandoned, and the acid titrated with sodium hydroxide solution in the presence of the copper sulphate using methyl orange as indicator. One might expect the end point to be so masked by the blue color of the copper in the solution as to render the method inaccurate, but by sufficiently diluting the solution it was found that perfectly consistent results could be obtained. When acid, the solution appears a deep purple; when alkali it is green; the end point chosen was that at which a trace of pink could be detected in the green solution¹. The sodium hydroxide solution was standardized by titrating against a standard sulphuric acid solution, which in turn was standardized against anhydrous sodium carbonate.

The results, shown graphically in the plots, are given in the following table:

Temperature, Degrees Centigrade	Concentration H ₂ SO ₄ , Gram Equivalents per Liter	Saturation Concentration CuSO ₄ , Gram Equivalents per Liter	Specific Conductance in Mhos.	Density Referred to H ₂ O
25.00	0.1488	2.818	0.05555	1.2140
25.00	0.4208	2.634	0.06884	1.2103
25.00	0.8680	2.457	0.1458	1.2070
25.00	1.345	2.320	0.2023	1.2115
25.01	1.876	2.181	0.2608	1.2130
25.00	1.914	2.153	0.2671	1.2165
25.02	3.077	1.837	0.4005	1.2162
25.01	3.659	1.649	0.4596	1.2229
				1.2227

For the effect of sulphuric acid on the solubility of sulphates see Engel, *Comptes Rendus*, 104, 507 (1887).

Electrochemical Laboratory,
Massachusetts Institute of Technology,
Cambridge, Mass.

¹ To indicate the degree of precision with which this titration can be carried out in a solution containing copper ions, the following results are appended:

Titration of NaOH vs. H ₂ SO ₄ , no copper present		Titration of NaOH vs. H ₂ SO ₄ in presence of CuSO ₄	
1 cc. NaOH = 0.9605 cc. H ₂ SO ₄	0.9594	1 cc. NaOH = 0.9541 cc. H ₂ SO ₄	0.9574
	0.9572		0.9585

Mean, 0.9590

Mean, 0.9567

The deviation of the two mean results is less than one-quarter of one per cent.

Japanese Porcelains From Chemical Point of View, and How to Improve Them*

EXHAUSTIVE investigations have been made by Yaichiro Kitamura on Japanese porcelains which have been known to possess the following compositions by authorities on ceramics since Hermann A. Seger's reports in the *Tonindustrie Zeitung* in 1891:

Bodies	0.3	0.4	RO.	1	Al ₂ O ₃	6.2	7	4	SiO ₂	
Glazes	1	RO.	0.41	0.55	0.59	Al ₂ O ₃	3.66	4.42	5.04	SiO ₂

The research of Oscar Kosert, published as a book, "Nippon Togyo" (Technology of Japanese Pottery), is a valuable contribution. His investigations were solely based on bodies. One of the results of his investigations was to show that the way of obtaining samples was not satisfactory. The non-uniformity of the burning tem-

TABLE I—CHEMICAL ANALYSIS OF JAPANESE PORCELAIN BODIES

(Descriptive details of minor importance about the variety of the samples are omitted by the abstractor)

perature in different parts of the kiln is great in Japanese kilns as compared with those of European types.

The varieties of bodies and glazes burned in Japanese kilns are plural and not single, as is generally found in Europe. At least two or three, sometimes four or five, varieties are found, each of which has a different burning point to meet the different temperatures of the successive sections of the kiln. For this reason, a great number of samples of varieties are important for the study of Japanese porcelain. There are a few reports as to the chemical compositions of Japanese porcelain; however, they do not give clear information about the bodies and glazes.

Y. Kitamura has devoted many years in confirming the chemical compositions of samples of all varieties from all representative localities, covering all typical lines of Japanese porcelain. From the investigations, he concluded some other formula than that of Seger should be applied to them.

Tables I and II show the analytical results of the bodies of fifty-nine varieties—8 from Aichi, 35 from Gifu, 8 from Saga Prefecture, and the rest from Kioto, Idzumi, Tobe and Hira Kiyomidzu. The limits of compositions in their molecular formula classified according to their localities are shown in Table III.

He analyzed all crude glazes before burning. There are 8 samples from Aichi Prefecture, 8 from Saga, 4 from Ehime and 5 from Yamagata. Their chemical compositions are given in Table IV.

*Abstract from "The Chemical Technology" (Kwagaku, Kogei), Vol. 2, No. 7, July, 1918.

Ehime Prefecture.....	1.83-3.14 RO	1 Al ₂ O ₃	7.14-8.35 SiO ₂
Yamagata Prefecture.....	1.63-2.64 RO	1 Al ₂ O ₃	7.52-8.92 SiO ₂
Total.....	1.01-3.14 RO	1 Al ₂ O ₃	7.14-12.94 SiO ₂

According to the above analysis, the Japanese porcelains have wider ranges of chemical composition both in bodies and glazes than have hitherto been believed by the ceramists. The new limits for them are as follows:

Bodies.....	0.26-0.57 RO	1 Al ₂ O ₃	4.68-8.21 SiO ₂
Glazes.....	1 RO	0.32-0.99 Al ₂ O ₃	2.27-8.26 SiO ₂

From the nature of their body materials, Japanese porcelains may generally be divided into two classes:

those bodies consisting of strongly plastic clays (their commercial names are Gainome and Kibushi) of one or two kinds, or with feldspar and quartz; and those having bodies consisting of quartz porphyry, or decomposition products of igneous rocks resembling the above, or these together with some auxiliary materials.

The majority of the so-called Japanese porcelains belong to the first class, which cannot be expressed by the old formula, and Seger's formula applies only to porcelains of Saga Prefecture.

The composition of glazes, on the whole, shows a considerable discrepancy with Seger's formula, and the author's report furnishes definite information.

HOW TO IMPROVE THE PORCELAIN FROM THE STANDPOINT OF CHEMICAL COMPOSITION

To improve the porcelain, he took the physical properties into consideration, for instance the percentage of breakage during transportation, durability, etc. Further, he compared these analytical results of the Japanese porcelains with the best ones having international reputations and tabulated the formulæ as follows:

Japanese porcelain, first type.....	0.36-0.57 RO	1.00 Al ₂ O ₃	4.68-7.01 SiO ₂
Japanese porcelain, second type.....	0.26-0.45 RO	1.00 Al ₂ O ₃	6.00-7.88 SiO ₂
Sevres, Vienna.....	0.3-0.35 RO	1.00 Al ₂ O ₃	2.8-3.5 SiO ₂
Limoges, etc.....	0.2-0.3 RO	1.00 Al ₂ O ₃	4.2-4.8 SiO ₂

For the best European porcelain bodies the value of RO is 0.2-0.35 equivalent and that of SiO₂ is 2.8-4.8 when Al₂O₃ is taken as unity. The first class Japanese porcelain bodies contain more RO and SiO₂ than those of Europe and the second class Japanese porcelain bodies usually contain about the same value of RO and sometimes a little more, but considerably greater value for SiO₂, and sometimes almost twice as much as those of Europe.

The presence of an excess of basic components in a body lowers the softening temperature of the body and makes it vitreous, thus resulting in the disadvantages of poor resistance to shock and other mechanical treatment. The silica has the property of rendering the body brittle, if present in excess, to a much greater extent than alumina.

To improve the mechanical properties of Japanese porcelain one possible way is to correct their composition by changing the proportions of the raw materials and bring them nearer to those of the higher grades. For the first class Japanese porcelain bodies, the alumina comes from plastic clay (Gainome clay), basic components from feldspar, silica from quartz. An increase of alumina and decrease of bases and of silica mean, respectively, an increase of Gainome clay and a decrease of feldspar and quartz in the mixing operation of the raw materials. By increasing the percentage of Gainome clay over the present proportion, plasticity is increased. The dyeing and burning shrinkages become considerable and unfavorable color effect is found in the burnt products. For these reasons, it is practically impossible to obtain good bodies by increasing their content of alumina over the present proportion by using the old materials alone.

The discovery of these Korean clays is, indeed, an important contribution to the ceramic industry. Their properties, compositions and application in porcelain bodies are fully described in Reports No. 10 and No. 13 of the Industrial Research Laboratory, Department of Agriculture and Commerce, Japan.

For the second class of Japanese porcelain the raw

materials are simply quartz porphyry of varied decomposition. In order to decrease the percentage of silica, it is necessary to introduce aluminous materials into the old body clays. These body materials are generally not of strong plastic nature, so the addition of strongly plastic clay should be to a certain extent effective.

When the silica content is considerably too large, the introduction of alumina, necessary to counterbalance the brittling effect of silica, in the form of plastic Gainome clay is not satisfactory, because of excessive drying and burning shrinkages. It is advisable to apply strong plastic Gainome clay mixed with some weak plastic chosen Korean clay.

For those of the second class of Japanese porcelain bodies which have an excess amount of basic ingredients, the introduction of clayey substance reduces the percentage of base in the bodies, but for those not having an excess of basic ingredients, corresponding amounts of feldspar are necessary to maintain the desired percentage of bases.

Refractories Industry in Japan

By T. KURAHASHI

WHILE every line of the chemical industry is rapidly growing and developing in Japan, the refractories industry has reached the highest development.

The manufacture of refractory material either in brick form or other is not a new industry there. About a thousand years ago Japanese began to manufacture refractories for iron and copper metallurgy, and made the

UNO FIREBRICK CO. INLAND SEA OF JAPAN

casting of the "Daibutsu," the gigantic bronze statue of Buddha. However, generally speaking, this industry is classified as one of the imported industries since Japan has opened her doors to Western civilization.

The Shinagawa Shiro-renga Kabushiki Kaisha (Shinagawa Firebrick Co., Ltd.) is the leading corporation of the brick industry and became the most important since the consolidation with the Nippon Yogyo Kabushiki Kaisha (Japanese Ceramic Co., Ltd.).

After the war broke out, and the chemical and metallurgical industries increased rapidly, many refractory plants were established. The Uno Taikarenga Kabushiki Kaisha (Uno Firebrick Co., Ltd.) is one of the most important.

Unfortunately, Japan has no variety of raw materials for special refractories, such as bauxite, magnesite, ganister, graphite, etc., so that most of the firebrick plants are not concerned in these special types of ware.

Tests of Men

WE GIVE herewith a few graphs taken from a recent number of *Science* on the "Measurement and Utilization of Brain Power in the Army" as developed by Major Robert M. Yerkes. They refer to psychological tests made of men in the Service, and their value is justified. They indicate: grade A, very intelligent; B, intelligent; C+, above average; C, average, C— below average; D, unintelligent, and D— and E, a mental age of from 7 to 10 years.

Without doubt the tests might be improved upon for special purposes, and those that are given do not include enough in number to demonstrate complete general averages. Nevertheless, as shown, they are confirmatory of what many of us have been thinking with more or less seriousness for a long time; that men in class D and under are not fit to rule. If all D— and E men had been rejected at the start, disciplinary cases would have been largely avoided, with all the delay, disturbances and expense attached to the proceedings;

PROPORTION OF LOW, AVERAGE AND HIGH GRADE MEN IN TYPICAL GROUPS

and the ranks of "poorest privates," "men of low military value," and "unteachable men" would have been greatly reduced.

We have been too neglectful of our D and E men and women in more ways than one. In mind they are children, and they are numerous, but we do not know how many they are, or which is which. The tests to determine this, though still inadequate, are better than we have been disposed to believe.

The present bolshevism and its associated I. W. W. anarchy are based upon the principle of rule by classes D and E. We make this as a postulate on the conviction that a psychological examination of the enrolled members of the I. W. W. by competent and impartial authorities would show a predominance of types D and E. It is easy enough to prove the contrary if the facts do not warrant the assertion. Now rule by men and women below type C is not to be endured unless those of types C and above are killed off, and then savagery is

bound to prevail, for children are, in a way, savages. In parts of Russia this practice seems to obtain now. Efforts have been made to establish it in the textile cities of Lowell and Lawrence, Mass., and there has lately been an unsuccessful attempt to make a start of it in Seattle.

We must not think for a moment that a man is of class D or E because he is a laborer, or that he is out of these classes if he is rich and in authority. Note, please, that over half of the enlisted men are above C-, and that a large proportion of sergeants and corporals are in classes A and B. Also we must bear in mind the number of commissioned officers in C and C+. We have not yet discovered the golden rule to fit men in places where they belong, but these tests seem likely to help us toward it.

The tests are probably weakest in ethics and esthetics. With the latter we have not much to do as yet in industry and engineering. But with ethics we have constantly to do; and ethics has a wider scope than the Ten Commandments of Exodus. The A and B mind may be unethical, and cause a veritable deluge of disaster without ever reaching the stage of discipline. The war and all its consequences are directly traceable to the disregard of ethics by the German nation and its people. Tests are unlikely to be a gage of ethics, because nearly everybody, whether good or bad, or wise or stupid, claims to be just and fair, and will use what intelligence he has to prove it in examination. Justice and fairness are functions of ethics. The chances are, however, that minds of the A and B types, even if unethical, will avoid doing things that will get them into trouble, and that their acts will be guided by the ethical standards of public opinion.

Here we have a new method of gaging men that is free from favoritism, and that judges each one for what he is. It does not ask who his father was, or whether he is rich or poor. He does not require a college degree or a high school diploma to rank A, nor will a doctorate in philosophy assure him of this standing. It provides a means to aid in avoiding incompetence in authority. But at the same time it carries with it certain obligations.

Two duties lie immediately before us in industry, and they are pressing, exceedingly pressing. We must test out the men we employ in order to fit them into

OCCUPATIONS

NO. CASES

their proper places. We must get rid of the system of hiring and firing by foremen, and we must know our men better.

That is one duty. The other is, we must set apart work that can be performed, at a living wage, by the D and E classes of men. They must be cared for, and watched, kindly but firmly. They should never be put into places of authority, whether they be rich or poor; and every such case should be tested and recorded. Then the A and B men should have the first chances of advancement, provided they are physically fit, and ethically adequate.

Cooks belong to a special class by themselves, and only the Lord and Tom Osborne know what to do with them.

DISTRIBUTION OF INTELLIGENCE RATINGS IN A TYPICAL ARMY GROUP, SHOWING THE VALUE OF THE TESTS IN THE IDENTIFICATION OF OFFICER MATERIAL

Some Points Regarding Calorimeter Efficiency*

Description of the Sources of Calorimetric Errors—Advantages of Different Types of Calorimeters for Moderately High Precision Commercial Work—Practical Conclusions—Superiority of a Calorimetric Installation With a Stirred, Thermostated Jacket and an Electric Thermometer

BY WALTER P. WHITE

THE use of the calorimeter is to-day extending rapidly, especially for fuel testing. At the same time some new types of calorimeters are being introduced whose value varies greatly, according to the work to which they are put. There is thus a double reason for considering the sources of calorimetric error and the advantages of different types of instrument. The present paper attempts this task, and does so with reference rather to the moderately high precision desirable in commercial work than to the higher precision attained in special researches.

Calorimetric experiments are practically always done by passing the heat to be measured into a known mass of water and observing the resulting temperature rise. The heat, ΔQ , is then determined in accordance with the well-known equation $\Delta Q = C\Delta\theta$, where $\Delta\theta$ is the temperature change and C the capacity for heat of the calorimetric body; that is, of the water together with the containing vessel. This determination would involve nothing but a couple of temperature measurements were it not for the fact that there is no insulator for heat, and therefore there is practically always some heat flowing to or from the calorimeter. This thermal leakage must be determined, usually by a combination of observations and calculations. It causes less actual error than is often supposed, but it dominates the whole subject of calorimetry, and is responsible for nearly all the characteristic features of calorimetric practice. Thus, in order to treat the leakage in a definite way the surrounding temperature must be controlled more or less; then, in order to prevent the leakage from making the calorimeter temperature non-uniform and therefore uncertain, there must be stirring, which is the reason for using a liquid. This, in turn, may bring difficulty from evaporation and irregular stirring, and, finally, some temperature differences remain uncorrected (especially in the solid parts) constituting "lags," which are, mathematically, the most complicated part of the whole subject, though they can, fortunately, be handled very simply in work of moderate precision.

SOURCES OF ERROR

Aside from blunders and exceptional occurrences, the sources of error in ordinary calorimetry seem completely covered by the following list:

- A. The main temperature measurements.
- B. The value taken for the heat capacity of the calorimetric body.
- C. The associated determination.
- D. The thermal leakage or its consequences, including:
 - a. Control of the external temperature.
 - b. Control of the calorimeter temperature (i.e., efficiency of stirring).

- c. The heat produced by stirring (which may be irregular, owing to irregular speed of stirring).
- d. Evaporation.
- e. Lags, if neglected or varying.

TEMPERATURE MEASUREMENT

A. The temperature measurement seems to call for little comment, save perhaps to say that from two to four individual observations are needed, so that the final error may be two or four times that of a single reading, though the average final error will not be so large as that. Thus, a mercury thermometer, if accurate to 0.001 deg., will, in itself, give a precision of one per mille or a little better with a temperature rise of 4 deg.; this is, however, rather high precision for a mercury thermometer. The electric (resistance) thermometer will do better—about ten times as well with the best instruments in competent hands. It of course requires a more elaborate installation. Many observers, however, consider the precautions and corrections needed with it less objectionable than those involved with the mercury thermometer, and the extra precision of the electric thermometer is a desirable thing, even in cases where the other may seem good enough. A precision which is just enough and no more for the purpose in hand looks very shrewd and economical on paper, and may prove not unsatisfactory so long as everything goes well; but if unexpected errors need investigation or checks upon the accuracy are desired, as is pretty certain to happen sooner or later, it is exceedingly comfortable to have even a fourfold or fivefold excess of precision, and in as many departments of the work as possible. The thermo-electric thermometer is not only capable of higher ultimate precision than the resistance thermometer in measuring small temperature differences, but is, to judge from my own experience, more reliable, and less troublesome in its need for precautions, though in some other evident ways it is less convenient. The methods necessary with it, however, are not so generally understood, and it is not regularly manufactured at present.

HEAT CAPACITY OF THE CALORIMETRIC BODY

B. For determining the heat capacity of the calorimetric body the practice of calibration by means of a known quantity of heat, obtained either electrically or by means of a standard substance, has so many advantages, and has already become so widely used, that no other seems to deserve consideration. With this method, if uniform conditions are preserved, the error of the calibration becomes little more than the average error of a number of determinations, which can be made as numerous as is desired.

C. The associated determination must be considered for a fairly evident reason. There is no such thing as

*Journal, Franklin Institute, Vol. 186, p. 279.

bottling up a quantity of heat for subsequent measurement; heat cannot even be passed, unchanged, directly from one calorimeter to another. The heat must be produced as measured, and the only way to give the measurement significance is to express it as a ratio between the quantity of heat and the quantity of the thing (reacting chemical, electric energy, etc.) yielding the heat. An error in one of the terms of this ratio has the same final effect as a corresponding error in the other. This is merely a formulation of what is pretty generally understood in individual cases. In commercial coal testing, for instance, it is generally recognized that the sampling of the coal is often the greatest source of uncertainty, and it is futile to strive for a calorimetric precision very far ahead of the uniformity which it seems worth while to seek in the sampling.

THERMAL LEAKAGE

D. The thermal leakage and its calculation are responsible, as has been said, for most of the problems and complications in calorimetry. In calculating, the leakage is taken as the product of the leakage modulus, or rate of leakage per degree of thermal head (thermal head is the difference of temperature between calorimeter and environment) multiplied by the integrated value of the thermal head for the experimental period. The standard method is to determine the leakage modulus by rating-period observations on the rate of cooling of the undisturbed calorimeter; if two such rating-periods are used, it is possible to determine the thermal head without measuring the environing temperature, provided this temperature does not change appreciably during the experiment. This procedure also eliminates the effect of the heat produced by the stirring, which would otherwise need especial attention. The method is familiar, and does not need detailed consideration here. This method is almost necessary if the environment consists of several indefinite bodies at different temperatures, but it involves having three observation periods. If, however, the leakage modulus is the same from day to day, and if the environing temperature is measured, or is kept at a known value by a thermostat, the leakage can, after suitable preliminary work, be determined merely from observations on the calorimetric temperature during the experimental period, and no other period is needed, unless occasionally as a check. Of course, this demands first that the environment be all at a single definite temperature—that is, practically, that it be a stirred body of water more or less completely enclosing the calorimeter (though with an air space between, of course), and second that the calorimeter always contain the same amount of water and always be located, to a fraction of a millimeter perhaps, in the same position within the jacket.

ACCURACY OF SPECIAL METHOD

To determine the leakage in this way not only saves time and labor, but may promote accuracy by eliminating the errors of the temperature measurements needed in observing the leakage rates. That is to say, instead of a rate determined separately with some error for each experiment, the observer uses a rate determined once for all with more accuracy by numerous experiments. Using this method, the Bureau of Mines observers have, as they state, usually attained in their regular routine procedure an agreement of 1 in 1000. Of course, this precision was realized only where the

sampling error was eliminated. This method, it may be added, should not be relied upon in any particular installation until it has been shown that the leakage modulus is in fact as constant as it needs to be. Other things than the position of the calorimeter may be of importance here. For instance, if metallic parts of any kind run from the calorimeter through the jacket to the air of the room outside it, a change in room temperature is very apt to alter the leakage rate unless proper precautions are taken. Evaporation is prevented in the Bureau of Mines calorimeters.

If the determinations made are nearly the same day after day, the temperature during the experimental period will always rise along almost the same curve, and its integrated value may without error be taken as the same for any given total temperature rise. If, in addition, the jacket temperature and the initial calorimeter temperature are always the same, the integrated thermal head will always bear the same relation to the total temperature, and the amount of thermal leakage will be simply a certain constant (and small) percentage of the total temperature rise. No attention, therefore, need be paid to the thermal leakage in working up the results. This is essentially the Bureau of Mines procedure. This treatment of the thermal head saves only a little labor, not time or error. Another important variation of the general method is obtained when the total value of the thermal head for the experimental period is kept very small. Since this value of the thermal head is the multiplier of the leakage modulus, a small value of it makes uncertainty in the modulus of very little importance; hence accuracy is higher while at the same time the modulus need not be very constant. In order to keep the total value of the thermal head small, the calorimeter is started at a suitable temperature below that of the jacket; the head is then first negative and afterward positive. It does not seem practical to use this method without observing the thermal head, nor without preventing evaporation. Hence this variation is a little more laborious, as well as more accurate, than the other. It does not take appreciably longer, and it avoids the thermostat.

CONTROL OF EXTERNAL TEMPERATURE

D, a. The temperature change from leakage of a well-designed calorimeter of ordinary size will be less than 0.015 of the thermal head in 5 min.; hence for 5-min. experimental periods the uncertainty of the jacket temperature may be at least thirty times that in the principal readings. Evidently any difficulty there may be as to this temperature will be a matter of control or uniformity, and not of measurement.

STIRRING

D, b and c. The matter of stirring seems fairly well covered by the recommendation of the joint committee on coal analysis of the American Society for Testing Materials and of the American Chemical Society¹, that the stirring be vigorous enough to heat the calorimeter nearly 0.001 deg. per minute, and regular enough so that the variation in heat is negligible. This is certainly sufficient with a reasonably well-designed calorimeter. The heat varies as the cube of the speed of stirring, so that a variation of 1 per cent in speed produces a variation of 3 per cent in heat production.

D, d. No data exist as to the relative probable error

¹*Jour. Ind. & Eng. Chem.*, 9, 106 (1917).

from evaporation, but this does not seem likely to be serious in commercial work, so long as evaporated water does not condense on the cover and drop back into the calorimeter. The prevention of evaporation is very desirable in work of high precision and is easy enough to be reasonable in nearly all cases, since it can be effected, without the introduction of any other error, by covering the calorimeter with an exceedingly thin metal cover. This cover need not bend down to touch the water, though it may well do so. If it does not, the water should be, to a millimeter, always at the same distance below it—say a centimeter. Covers of wood, rubber or other poorly conducting material have no other recommendation than possible cheapness. (See Walter P. White: "Calorimetric Methods and Devices," *J. Am. Chem. Soc.*, 40, 1888, 1918.) It does not necessarily follow that it is desirable to scrap such covers now in use, however.

FURTHER PRACTICAL CONCLUSIONS

From the preceding discussion it appears that the uniformity of conditions in the uniform determinations of commercial work is almost sufficient in itself to secure precision, so far as thermal leakage is concerned, since effects which would otherwise be errors tend to cancel. The joint committee report cited above says that the calorimeter jacket "should" contain water which is stirred. There are two different reasons for this. The uniform temperature of a stirred jacket is, of course, desirable, but it might not seem necessary, since an unstirred jacket always started at the same temperature relative to room and calorimeter would be likely to give uniform results. But to have a jacket full of water which is stirred is the easiest way to provide for getting it at the same relative temperature each time; moreover, the provision of this particular feature is seldom likely to prove expensive.

To convert the stirred jacket into a thermostat is more expensive, since it requires a regulator and also demands if it is to be of real value that the jacket be brought above the calorimeter so as to surround it with practical completeness. But the gain in time and labor from using such an installation is very considerable.

The joint committee report advises having the initial calorimeter temperature so far below that of the jacket that the final temperature is less than a degree above it, and the total resultant thermal leak is near zero. Two advantages are attributed to this procedure; one, that evaporation is diminished; the other, that the total leak is small. The diminution of evaporation is as likely to increase the error as to decrease it, and the smallness of the total leak is practically of no advantage in the case treated, where two rating periods are supposed to be run, since in that case the total magnitude of the leakage has no effect on the error. This is proved in: Walter P. White: "The Conditions of Calorimetric Precision," *J. Am. Chem. Soc.*, 40, 1877, 1918. Little is lost by thus reducing the total amount of leakage, but it would be misleading, in considering the adoption of this method rather than some other, such as the Bureau of Mines method, to suppose that it had any real advantage in this particular direction.

It has been shown above that where a predetermined value of the modulus is used the reduction of the total

amount of leakage does increase the accuracy. That case is not to be confused with the present one, where two rating periods are to be run (or three in all), and was not contemplated in the joint committee report. The reason for the difference in the two cases is this: With a predetermined modulus the heat of stirring is known, and so is the value of the envolving temperature. When the direct thermal leakage is made very small its error is also made small, and there is nothing else normally affecting the calorimeter temperature, but with the 3-period method the heat of stirring and the effect of the envolving temperature are determined along with the main thermal leakage, and so even if the main leakage is made to disappear the determination of these quantities remains, and its error is in fact about the same whether the total correction is large or small, since the term containing these quantities is not multiplied by the small value of the thermal head. A more complete explanation is given in the reference cited.

A calorimeter has been advertised as "adiabatic" which is characterized mainly by the use of a vacuum-jacketed glass vessel instead of the usual metal cup. To call such an arrangement adiabatic is pure humbug; it has a thermal leakage, which may be one-third or may be one-fourth as great as that of an ordinary calorimeter. To claim some advantage from the smaller leakage is legitimate; for it may enable an equal degree of precision to be reached with less care as to conditions.

Attempts are being made to utilize in commercial work calorimeters which are really adiabatic; that is, in which the jacket temperature can be rapidly changed and controlled so that it can be kept the same as that of the calorimeter during an experiment. Some of the proposed apparatus is admirable in its ingenuity and effectiveness, but there is still reason to doubt if it is worth while. The adiabatic method in calorimetry, like most methods in every subject, differs greatly in value according to the conditions of its use. In aneroid (fluidless) calorimetry and in long-timed determinations it is often absolutely indispensable, but in short experiments its value is much less. If we refer to the sources of error listed in this paper, *A*, *B*, and *C* are scarcely affected one way or the other by the adoption of the adiabatic method; nor are the temperature distribution effects *D*, *b*; *D*, *c*, and *D*, *e*. Evaporation (*D*, *d*) is greatly diminished, but easier ways have already been given of securing this result, which is not of first importance, anyway, in commercial work. The control of jacket temperature (*D*, *a*) will evidently be more perfect where this temperature is not greatly changed, so that here the adiabatic method is actually worse, though the inferiority is probably not serious. One real advantage of the adiabatic method is in ease, not precision, and consists in the avoidance of the labor of calculating the thermal leakage. But in commercial work this advantage is still more easily obtained through a thermostat, as at the Bureau of Mines. Of course, this method calls for a constant leakage modulus, which the adiabatic does not. But the results show that the chances of error from inconstancy of this modulus are very small. The most serious danger of variation in the modulus—that coming from the influence of room temperature changes—is quite as great with the adiabatic method. In uniform short-timed determinations, then, the adiabatic procedure, in return for the expense

²Owing to the fact that the leakage rate differs some 30 per cent. according as evaporation is or is not occurring; that is, suddenly becomes 30 per cent. greater when the calorimeter temperature passes above the jacket temperature.

and manipulation it demands, appears to offer no advantage that cannot be more easily secured in other ways².

If a massive block of metal is used as the calorimetric body, equalization of temperature is less perfect than with a stirred liquid, but the difficulties and annoyances of stirring and evaporation are completely banished. The relatively imperfect equalization is evidently less serious in the uniform determinations of commercial work, so that for such work this kind of calorimeter might prove very desirable. Féry has proposed such an instrument, using the steel bomb alone as the calorimetric body, and measuring temperature thermoelectrically. In striving for simplicity, as it seems to me, he has attained an altogether unnecessary crude-

ness in several respects. Apparently, a much more accurate instrument could be realized which would not be harder to manipulate. The final success of such an instrument—that is, its net superiority to existing calorimeters—cannot be guaranteed in advance of actual experience, but the idea seems promising.

In conclusion, it may be said that a calorimetric installation with a stirred, thermostated jacket and an electric thermometer appears thus far to have given the best combination of precision and ease of operation, and that in the main the electric thermometer is responsible for the precision, and the thermostat for the ease of operation.

An Adiabatic Bomb Calorimeter

By E. B. HOLLAND,* J. C. REED,† AND J. P. BUCKLEY,‡

THE USE of calorimeters has become so general in both investigational and trade laboratories and the literature on the subject is so voluminous that it is with some reluctance that one offers additional material for fear of repeating what may have been more ably presented elsewhere. Some nine years ago the Massachusetts Agricultural Experiment Station secured a Berthelot-Mahler-Kroecker calorimeter with copper jacket and accessories, including pellet presses, Richter-Beckmann thermometers, Muencke balance, etc., for use in nutrition work and in the examination of fuels. The apparatus is too well known to require a detailed description. The bomb is of 300 cc. capacity and convenient to handle except in a few minor details. The porcelain lining is the most vulnerable feature. The jacket, however, did not permit the control of temperature required in an adiabatic calorimeter, and the reciprocating stirrer was unsatisfactory.

NEW CONSTRUCTION

A new double-walled copper jacket was constructed by E. A. Thompson of Amherst, the details of which are shown in the illustration. It is provided with an inlet for cold water, an overflow, a screw propeller stirrer belt driven by a slow starting electric motor of $\frac{1}{2}$ hp., speed 1800, and a helical electrical resistance heater, which together permit complete control of the temperature of the jacket. The entire amount of water in the jacket circulates freely, as there is no dead space. The heater raises the temperature of the water 1 deg. C. per minute of current use. The cover is of a "two-step" type, copper with hard fiber top and partition, thus providing two superimposed dead air spaces. The thermometer and lens supports are of simple construction and very serviceable.

The copper pail, containing water in which the bomb,

stirrer and thermometer are immersed, is insulated from the jacket and accurately centered by means of hard fiber supports. The pail, water, bomb, stirrer, etc., constitute the calorimeter proper, and the hydrothermal equivalent of the metal parts, enamel, glass, etc., together with the water, compose the bomb unit. A rotary stirrer of skeleton construction, with an offset for immersing the thermometer and two sets of blades inclined in opposite directions, effects with the baffle plates on the pail a spiral movement of water horizontally around the bomb. The stirrer is driven at low speed by a secondary belt leading from the screw propeller in the jacket and insures equalization of temperature without the production of an appreciable amount of frictional heat. The wires leading from the bomb are soldered to insulated cylindrical pieces of spring brass which slip over the terminals, displacing the screw connections, and pass out of the jacket through the driving shaft of the rotary stirrer to the desk terminals.

The calorimeter can be easily assembled or dismantled in a few minutes. The water and electrical connections permit convenient control of both screw propeller and rotary stirrers, temperature of jacket, thermometer taper and ignition.

THERMOMETERS

In the selection of new thermometers for determining the heat of combustion, choice lay between the normal type and the metastatic with an arbitrary zero, such as the Richter-Beckmann. The electrical resistance type which has since come in vogue seems to possess a high degree of accuracy and ease of reading, but was not considered at that time. The latter instrument was developed largely by the Bureau of Standards. The cost, however, precludes its use by many laboratories today.

Normal and metastatic thermometers of substantially the same length scale, 6 deg. range and 0.01 deg. divisions, could be readily procured and were presumably equally sensitive. The normal type of special construction was considered preferable and finally selected. The following specifications were furnished:

Approximate total length	24.0 in.
Length of scale, 16 to 22 deg. C.	10.0 in.
Outside diameter on the scale	0.5 in.
Length below scale plate	8.0 in.

Each thermometer was provided with an expansion bulb, milk glass scale and a metal cap to permit the use of a taper. After seasoning for several months the thermometers were tested by the Physikalisch-Technischen Reichsanstalt and a certificate of correction for each degree issued.

²In some recent work of high precision (*Journal Am. Chem. Soc.*, Vol. 39, p. 2110, 1917) the adiabatic method was adopted mainly because a stationary final calorimeter temperature was thought necessary for satisfactory reading of the resistance thermometer. It is safe to say that the necessity, in so far as it existed, may fairly be attributed to some deficiency or peculiarity of the electric installation used, and is not an inevitable disadvantage of that type of thermometer, although the usual installation is not the most convenient that could be used for reading changing temperatures. So far as the precision of commercial work is concerned, there appears to have been no general difficulty in reading changing temperatures, as is indeed shown by the disregard of the possibility of making their reading more convenient.

*Associate chemist, Massachusetts Agricultural Experiment Station.

†Assistant chemist, Massachusetts Agricultural Experiment Station.

ADIABATIC BOMB CALORIMETER

Almost any chemical thermometer graduated to 0.1 deg. C. on milk glass scale or stem will answer for determining the temperature of the water jacket, provided the instrument is reasonably accurate.

The tapper was constructed from an ordinary electric bell clamped to the arm of the thermometer support, the gong removed and a piece of soft rubber inserted in place of the hammer to reduce the force of the blow to the intensity desired. Wet and dry cells having proved unreliable, the tapper was run from a bell ringing transformer giving 5 to 10 volts, 0.75 amp. vibrating and 1.30 stationary. The application of the tapper a few seconds before each thermometer reading prevented any perceptible mercury "lag" or frictional error.

LENS

The lens sent with the original calorimeter for reading the thermometer scale was unsatisfactory. A Galileo telescope, a reading telescope and a so-called "laboratory microscope" were also tried with like results. The ideal instrument should be mounted horizontally, give a clear sharp field of appreciable size when applied to the opaque milk glass scale of the thermometer, not invert the object, magnify sufficiently at 0.01 deg. C. division of the scale (approximately 0.42 mm.), so that it can be readily and accurately divided into 10 parts or read to 0.001 deg. C. (probably equivalent to 15 to 20 diameters), and if possible have a focal distance of about 90 mm., so as to clear the side of the calorimeter jacket. Singly all these requirements were possible, but combined were rather difficult to meet.

The prism tube of a Pfeiffer's dissecting microscope with ocular 201 and a chromatic objective 1-a with special arrangement for varying the focal distance was finally secured. The combination gives a magnification of approximately 4.5 diameters, and a clear field of 48

mm. at a distance of 90 mm. The instrument as a whole is the most satisfactory of any tested, though lacking the necessary magnification. The latter fault will be remedied as soon as higher power can be secured, which so far has been impossible on account of the war.

Amherst, Mass.

Meeting of the Maritime Chemists' Association

At the meeting of the Maritime Chemists' Association held in Sydney, N. S., on July 15 and 16, Mr. A. F. Blake, chief chemist of the Atlantic Sugar Refineries, Ltd., St. John, read a paper on "The Evaluation of Coal," in which he developed an equation based on the analysis of the coal to determine the value as a fuel. He also showed a nomographic chart enabling the solution of the equation to be carried out with a minimum of effort.

Mr. I. C. Mackie, chief chemist of the Dominion Iron & Steel Co., Sydney, read a paper on "The Use of Benzol as Motor Fuel," which appears in a forthcoming issue of the *Canadian Chemical Journal*.

Dr. H. Jermaine Creighton of Swathmore, Pa., read a paper describing the Landreth direct oxidation process for the electro-purification of sewage, showed lantern slides of the plant and gave analytical and bacteriological data showing the efficacy of this method. He also gave cost data for an installation.

A paper by Dr. A. McGill of the Trade and Commerce Department on "The Chemists' War" was read by title.

Committees were appointed to deal with the question of the formation of a section of the Society of Chemical Industry and to approach the Government relative to the representation of the Maritime Provinces and its industries at the forthcoming Exposition at Chicago.

Notes on the Estimation of Metallic Zinc Content of Zinc Dust

BY W. F. EDWARDS

BY USING the Franz Meyer apparatus and observing all of the numerous required details one can obtain quite accurate, consistent results in the chemical analysis of new (unused) zinc dust; and by the exercise of proper care and precautions fairly consistent results can be obtained also on zinc dust that has been used in the process of sherardizing.

However, everything taken into the consideration, the hydrogen gas method is not suited to the estimation of zinc dust, used or unused, in sherardizing. It requires too long time, too much attention to details and too much apparatus. Barometer readings, temperatures, vapor tension corrections, gas absorption corrections, etc., are necessary.

The method of estimating the metallic zinc in zinc dust by the reduction of potassium iodate in dissolving the zinc dust in a strong solution of fixed alkali and subsequent titration of iodine distilled from the acidified solution by sodium thiosulphate, in the main as given in the second edition of "Merck's Reagents, Their Purity and Tests," gives consistent results when proper attention is given to a number of details such as continued shaking during the solution of the zinc dust, proper cooling of the solution of potassium iodide in which the iodine is absorbed when distilled from the acidified solution, and proper attention to connections in and displacement of the air from the distillation apparatus. This method, like the hydrogen gas method, is subject to too many details to be a good working method in sherardizing or other commercial plants.

THE AMALGAM METHOD

The amalgam method gives very uncertain results, but in general it may be said to give too high per cents of zinc oxide and therefore by difference too low per cents of metallic zinc. As usually described the amalgam method depends on the titration of the excess of a measured quantity of standard acid, usually hydrochloric acid. It is not easy to get a definite end reaction in an acid solution containing zinc salts, as the zinc hydroxide formed does not show sharply enough the point at which the acid is neutralized by the standard alkali solution. By titrating the acid solution of zinc salts with standard solution of potassium ferrocyanide to obtain the zinc directly instead of by deduction from the amount of acid used, one can get a definite enough end reaction for practical purposes, if the solution is filtered before titration. However, the amalgam method can only be of value when carried out with careful attention to details in parallel estimations of the "unknown" zinc dust and standard zinc dusts of known metallic zinc content, under identical conditions of reagents, temperature and time. Even under such conditions the results are not even satisfactory for ordinary practical purposes.

THE FERRIC AMMONIUM ALUM METHOD

The method of reduction of ferric sulphate in my hands gave very inconsistent results even when care was taken to run parallel estimations as nearly in the same way as practical. However, with crystallized ferric ammonium sulphate (ferric ammonium alum) I was able to get very satisfactory results both as to consistency and accuracy, the results comparing favorably

with those obtained by the hydrogen gas method, the time being approximately 15 min. instead of from 6 to 36 hr., the approximate time limits for the gas method. The process is satisfactory when 1 g. of zinc dust is weighed into a 600 cc. Erlenmeyer flask and 50 g. of the ferric ammonium alum in crystals (the larger the better) and 100 cc. of water added. The mixture should be kept in constant stirring motion by giving a suitable motion to the flask. The crystals of ferric alum aid in stirring the zinc dust and will usually not all be in solution when the zinc dust is dissolved. As soon as the zinc dust is all dissolved add 100 cc. of 1 to 10 sulphuric acid and titrate with N/10 potassium permanganate solution. In case there are many analyses to be made it saves calculation to use a potassium permanganate solution each cubic centimeter of which represents 1 per cent of zinc on a 1 g. sample.

COMPARISON OF RESULTS BY DIFFERENT METHODS

The results are quite accurate enough for the estimation of the metallic zinc content of used or unused zinc dust in sherardizing plants. The following analyses of used and unused zinc dust by the hydrogen gas method and the ferric ammonium alum method were made from the same sample in each case and show a very close comparison:

NEW ZINC DUST			
Hydrogen Gas Method		Ferric Alum Method	
	Per Cent		Per Cent
No. 1.....	94.9	No. 1.....	94.7
No. 2.....	94.9	No. 2.....	94.7
No. 3.....	94.8	No. 3.....	94.6
No. 4.....	95.1	No. 4.....	94.5
No. 5.....	95.3	No. 5.....	94.6
Average.....	95.0	Average.....	94.8
USED ZINC DUST			
Hydrogen Gas Method		Ferric Alum Method	
	Per Cent		Per Cent
No. 1.....	79.4	No. 1.....	79.7
No. 2.....	78.8	No. 2.....	79.6
No. 3.....	78.6	No. 3.....	79.7
No. 4.....	79.5	No. 4.....	79.8
No. 5.....	78.4	No. 5.....	79.8
Average.....	78.9	Average.....	79.7

In the case of the hydrogen gas method on used zinc dust I was unable to get a completed reaction in less than 24 hr., the time being more often 36 hours. Attempts to speed up this method by using stronger acid than usual led to freak speeds that gave unsatisfactory results. I have not made any attempt to explain the freaks.

On the whole I think I am justified in stating that the ferric ammonium alum method of estimating the metallic zinc content of both used and unused zinc dust is quite satisfactory for all practical purposes.

Civil Service Examinations

Metallurgist.—A vacancy in the Bureau of Mines, Pittsburgh, Pa., at \$2700 a year will be filled from this examination. In addition to a college degree, the applicant must have had four years' experience in metallurgy, at least two years of which must have been in aluminum and magnesium foundry and rolling practice. Applications must be filed by Aug. 26, 1919.

Research Chemist.—The duties of this position include research chemical work in connection with iron, steel and associated alloys or refractories and gases, as assignments will be made in the Ordnance Department at Large, War Department, for duty at ordnance establishments throughout the United States, at a salary of \$2200-\$2500. Examination closes Sept. 2, 1919.

PLANT OF KINGSPORT WOOD REDUCTION CO., KINGSPORT, TENNESSEE

A New Method of Distilling Both Green and Seasoned Hardwoods

OUR readers are more or less familiar with the Government's urgent need for large quantities of chemicals in its warfare activities. However, some of us may not have realized the extreme importance of acetone and acetates in our aircraft production program, these being essential ingredients in the dope applied to aeroplane fabrics.

The Government's requirements so far exceeded the nation's possible production from the available supply of dry or seasoned woods that the authorities welcomed a new process which would procure these and other products from green wood, sawdust or wood-waste quite as well as from seasoned cordwood. It takes about twelve months properly to season cordwood preparatory to destructive distillation by what we may now term the old line process.

The new process has for its chief points of advantage a method of briquetting sawdust or finely divided wood-waste and of distilling the wood briquets under controlled conditions of temperature and pressure in multitubular retorts.

The briquetting machines, the invention of Mr. Otho C. Duryen, have been in use for about three years briquetting brass and copper borings and turnings at plants located at Waterbury, Conn., and Chicago.

The material is compressed in a specially designed press. One of the plungers of this press is driven against the compressed charge by the explosion of a gas-mixture in an auxiliary cylinder. The resultant impact produces the briquet.

Tests were made to satisfy the Government that sawdust, or "hogged" and shredded wood, could be similarly briquetted, after drying; that the supplementary processes of shredding, distillation in multitubular retorts, the recovery of pyroligneous acid and its constituents, wood alcohol and acetate of lime, were thoroughly practical on a large scale.

The Kingsport Wood Reduction Company contracted to erect and operate a plant using this process, the only one of its kind in the world. Accordingly a 35-acre site was selected near the city of Kingsport, Tennessee, in the mountains about equidistant from the Virginia and North Carolina boundaries. This location was chosen because it tapped an area in which a valuable supply of hardwood sawdust was available from the scores of mountain saw mills in the three adjoining States, also because of the large available supply of

standing hardwood timber. The timber belt upon which the plant depends for its current supplies extends for more than one hundred miles in every direction.

Ground was broken in April, 1918. Buildings and equipment costing over a million dollars were rushed toward completion with such vigor that the armistice of the following November found the plant practically ready to make initial deliveries.

HANDLING THE RAW MATERIAL

Trainloads of sawdust and wood-waste are received on an elevated trestle in drop-bottom cars, the cars being emptied into bins alongside the process building. The sawdust and fine material is carried by a conveyor direct to rotary screens located in the process building. The cordwood, either green or dry, together with slabs and other coarse wood-waste, is carried by conveyor into two "hogging" machines in the same building, where it is "hogged" and shredded prior to being briquetted. Both the sawdust and shredded wood pass through cylindrical screens and from these to special patented rotary driers by means of conveyor system. The driers are about 8 ft. in diameter and 60 ft. long and are heated by coal. Their operation is so flexible and efficient that however wet the entering sawdust may be the product emerges as a steady stream in a completely dried condition.

BRIQUETTING THE PROCESSED WOOD

From the rotary driers an automatic conveyor carries the dried sawdust and shredded wood up an incline into eight storage bins in the top of the press building. In this building is located a battery of eight briquetting presses, one for each storage bin.

The material feeds by gravity from each bin into a high-speed rotary shutter, which fills the briquet mold. Every two seconds the horizontal plungers of each of these machines move inward toward each other and when the eighteen inches of sawdust are compressed into a space of about five inches, the explosion takes place and the resultant shock, aggregating many tons to the square inch, impacts the material into a briquet two inches thick and four inches in diameter. The wood briquet weighs approximately one pound and is heavier than water.

DISTILLING THE WOOD BRIQUETS

As the briquets are discharged from the presses, they roll down through chutes into a storage bin at one end of the adjoining retort building. Here a novel assembling device sets them on edge, like lozenges in a package, in angle-iron troughs 20 ft. long. The filled troughs are lifted onto a charging car, which is moved

¹U. S. Patent, 1,259,733.

forward to the doors of the retorts, of which there are 26 in this building.

The retorts are a multiplication of steel tubes of about 5 in. internal diameter and 20 ft. long, heated by a battery of gas burners. The retort tubes are larger in their inside diameter than the wood briquets, to allow space for the escape of the gases and the heavier liquid products. As the charging car is brought in alignment with a retort, the front and rear retort heads are raised and a mechanical pusher shoves the briquets into the tubes, forcing the red-hot charcoal of the previous heat out at the other end of the tube.

A heat takes about two and one-half hours. The temperature is under such accurate control as to drive off each distillate at the temperature most favorable for both quantity and quality production. During the heat, hydraulic compression plungers exert a pressure against the charge of now plastic briquets. This control of the compression of the charge, together with the accurate control of heat, produces a charcoal of such density and uniformity that its power for absorbing gases has been hitherto unequalled. As the process developed, it was discovered that the tars and oils and their products take on equally unusual characteristics, which, it is claimed, will give them distinctive commercial value.

RECOVERING THE DISTILLATION PRODUCTS

The gaseous product, pyroigneous acid, passes through copper piping from the condensers to the stills, while the tar is piped to the tar stills. Subsequent distillation of the pyroigneous acid produces acetic acid, wood alcohol, oil and tar residues.

The alcohol is pumped from the still house into two large steel storage tanks. The acetic acid is drawn off into mixing tubs, where it is combined with calcium oxide to form acetate of lime. Drum driers revolving in these tubs pick up a film of the solids, which are scraped off by a steel knife and deposited on a horizontal belt conveyer. This conveyer, in turn, delivers the pasty product to a broad endless drier belt formed of interwoven steel links which become covered and enmeshed with the plastic material. Drying is accomplished during the passage of this belt upward and downward through a series of gas heated tile flues extending from floor to ceiling of the tall building. The acetate of lime is thus baked onto the chain belt, and at the end of its travel it encounters a series of sharp turns which crack the caked acetate off the chain and deposit it in granular forms on a movable conveyer. It is then sacked and delivered by a chain conveyer directly into freight cars.

REFINING THE TAR

The tar from the retorts is carried directly to the tar stills, where it is refined and the creosote, oils, pitch and other wood-tar products are recovered. Provision has been made for enlarging and extending the tar distillation and refining facilities of the plant to meet the requirements of the various markets that may develop.

The plant as it now stands has a capacity for handling one hundred cords of hardwood per day, or its equivalent in sawdust and wood-waste. This is approximately two hundred tons of dry wood or from three hundred to four hundred tons of green or wet wood. With the cessation of hostilities the Government's demand for these essential products ended, but arrangements are being perfected for the operation of the plant along commercial lines by its builders.

Jordan Scientific Society of Bates College

AN INTERESTING example of the manner in which a student organizations can aid in arousing public interest in scientific developments—particularly those of applied science—is afforded by the activities of the Jordan Scientific Society of Bates College at Lewiston, Me.

In 1918 an exhibition of some of the work done by members of the society was held, primarily for the purpose of interesting nearby high-school students in the college. The first exhibit proved such a success that this year the scope was increased to include local business men and the general public.

Every course offered in chemistry at Bates was represented by an exhibit with work being done by students just as it is done in the laboratories. Thus in general chemistry students prepared nitric acid, while in industrial chemistry various commercial analyses were carried out. In the advanced organic preparations several dyes manufactured in the college laboratories were shown. Lewiston is a thriving textile center with ten cotton and woolen mills, hence work in textile chemistry was featured at the exhibit, and more than one mill agent made favorable comment on this feature. National manufacturers have co-operated with the department of chemistry by sending permanent exhibits of their products and the raw materials entering into their manufacture until the department has over forty exhibits illustrating most of the important chemical industries. These were placed on exhibit with proper placards and formed one of the most interesting parts of the exhibit to the general public. In fact this exhibit was somewhat of a miniature reproduction of the National Chemical Exposition.

The programs of the society meetings were made more interesting by the use of moving pictures to illustrate papers. Films were obtained through co-operation with the Bureau of Commercial Economics and national manufacturers and included such subjects as "Operation of a By-Product Coke Oven," "Operation of a Pulp and Paper Mill," "Refining of Sugar," "Cyanamide Process," and "Cottrell Precipitation." In addition to papers explaining these processes, other members have given original papers on "Synthetic Rubber and Rubber Substitutes," "Dehydrated Foods," "Radium Emanations," "Use of the Spectroscope and Spectrometer in Spectrum Analysis," with plates prepared in the Bates laboratories; "Gas Warfare," and "The Fourth Dimension."

The Society was exceedingly fortunate in securing for one of its speakers Dr. H. E. Williams, research chemist with the S. D. Warren Paper Co. Dr. Williams spoke on "Black Liquor" and showed some of the products which he had been able to recover from it. Dr. Williams has the distinction of being one of the few men in the United States who is an authority on this phase of the paper industry.

This short sketch of the activities of the Jordan Scientific Society is given with the hope that some other college may find them as worth while as they have proved at Bates. Many of the large Western colleges are using moving pictures to good advantage; so far as is known, Bates is one of the few Eastern colleges to use films. The idea of an exhibit by a student organization of a college is believed to be original, but capable of great development.

Alignment Chart for the Gas Laws

BY ALAN G. WIKOFF

WHILE the Boyle-Mariotte-Charles law, $pv = RT$, is applicable with a high degree of accuracy only to the permanent gases at pressures below three atmospheres, the relation

$$\frac{pv}{T} = \frac{p'v'}{T'}$$

which is derived from this law, is constantly employed in practical work for the calculation of gas volume under different conditions of temperature and pressure. In the accompanying alignment chart for the solution of this equation, the necessity of converting deg. C. into deg. absolute is avoided by graduating the temperature scales *A* and *I* so that the scale reading in deg. C. corresponds to the logarithm of the absolute temperature.

There are two pairs of p , v and p' , v' scales, one pair having the index at the bottom of the chart, the other near the center. The advantage of such a construction is evident when we consider the actual operation of the chart. Let the unknown be p' , v' or T' , all the other values being known. Starting with p , v and T , the

product, pv , is first obtained by joining the numerical values of p on scale *B* and v on scale *D* by a straight line, giving a point of intersection on *C*. Since we are not interested in the numerical value of this product, this scale is not graduated. If this point on *C* is now connected with the value of T on *A*, we obtain a point on *E* which represents the quotient, $pv \div T$. Here again, the numerical value is not required. If T' is known, connect the value of T' on scale *I* with the point on *E* and obtain a point of intersection on *G*, which, aligned with the value of v' or p' (whichever is known) on *F* or *H*, gives the unknown on either *H* or *F*. If T' is unknown, first obtain the point $p'v'$ on *G* and align this with the point on *E*, giving the value of T' on *I*. If, when using scales *B* and *D* for p and v , the point $pv \div T$ does not fall within the limits of the chart on *E*, the values of p and v should be transferred to scales *B'* and *D'* and the corresponding pair $F', *H'* used for v' and p' . (See example II below.)$

Since the chart is symmetrical about *E*, all of the operations may be carried out on one side, as shown in example IIA. The extended form is given, however, in order that the principle may be more readily grasped.

Example I: Given 525 cc. of oxygen at 820 mm. and 350 deg. C.; what is the volume under standard conditions (760 mm. and 0 deg. C.)?

$v = 525$ cc. $v' = x$
 $p = 820$ mm. $p' = 760$ mm.
 $T = 350$ deg. C. $T' = 0$ deg. C.
 $pv \div T$: Align 820 on *B* with 525 on *D*; obtain point *a* on *C*.
 $pv \div T$: Align 350 on *A* with *a*, obtain point *b* on *E*.
 $(pv \div T) T'$: Align 0 on *I* with *b*; obtain point *c* on *G*.
 $p'v'$: Align 760 on *H* with *c*; obtain x = 248 on *F*.
 Example II: Given 5 liters of a gas at 80 cm. and 150 deg. C.; at what temperature would the volume be 6.5 liters when the pressure had been reduced to 40 cm.?

$v = 5$ l. $v' = 6.5$ l.
 $p = 80$ cm. $p' = 40$ cm.
 $T = 150$ deg. C. $T' = x$

$pv \div T$: Align 80 on *B'* with 50 on *D'*; obtain point *a'* on *C*.
 $pv \div T$: Align 150 on *A* with *a'*; obtain point *b* on *E*.
 $p'v'$: Align 6.5 on *F'* with 40 on *H'*; obtain point *c* on *G*.
 $p'v'$: Align 40 on *F'* with *c*; obtain x = -100 on *I*.
 Example IIA: Same problem as Ex. II showing method of solution, using only one side of the chart.
 Obtain b' as above.
 $p'v'$: Align 6.5 on *D'* with 40 on *B'*; obtain point *c'* on *C*.
 $p'v'$: Align 150 on *A* with *c'*; obtain x = -100 on *I*.

Uses of Manganese Dioxide Ore*

BY W. C. PHALEN

ESTIMATES of the quantity of manganese ore used in the industries other than the metallurgical industries vary from 25,000 to 50,000 tons per annum. The latter figure is probably more nearly correct. Most of the ore so used is the highest grade of pyrolusite (MnO_2) obtainable and commands a much higher price than metallurgical ore. The manganese dioxide ore is generally spoken of as chemical manganese ore.

The principal use of manganese ore aside from its applications in the steel industry in the form of ferromanganese and spiegeleisen is as an oxidizing agent. It is so used principally in the manufacture of dry cells, as a decolorizer in certain kinds of glass, and as a drier in oils, paints and varnishes. The ore is also used directly or indirectly in the manufacture of various manganese chemicals. Many of the textbooks describe its reaction with hydrochloric acid as a source of chlorine. It is no longer used commercially in making chlorine gas, as the latter is an abundant by-product in the manufacture of caustic soda and potash. Some chlorine may be made by this method when the object is the production, not of chlorine, but of manganese chloride. It has been mentioned as a soil stimulant, but its value in the fertilizer industry has not been established and so far as known it is not a constituent of any commercial fertilizers. Only those uses of commercial importance will be mentioned here.

The Dry Cell

GENERAL DESCRIPTION

To understand fully the rôle played by manganese dioxide in the dry cell, it will be necessary to explain the general make-up of the cell, the chemistry of the processes involved, together with the constituents entering into the reactions.

The modern dry cell, commonly but erroneously called the dry battery, is a portable modification of the "Disque" Leclanché cell invented by Leclanché about 1868. This consisted of a porous cup containing a carbon electrode and a mixture of rather coarsely ground retort coke and pyrolusite. The cup was sealed over, two vents being left for the escape of excess gases, and was placed along with a zinc rod in a glass jar containing a solution of ammonium chloride. Because of its simplicity and ease of operation, many attempts were made to fix the electrolyte in various media such as sawdust, gelatin, asbestos and silicic acid, so as to make it portable.

In 1888 Gassner brought out the first really successful dry cell. The positive pole consisted of a cylindrical mass of ground pyrolusite and coke packed in a canvas bag around a carbon electrode. This was placed in a zinc container which also served as the negative pole, and a paste of plaster of paris, zinc chloride and ammonium chloride was poured under and around it. After a short time, the paste would set and then the cell was sealed with a rosin or pitch composition.

The Gassner cell, though a great improvement over various other dry cells of the time, did not meet with much favor because of its high internal resistance and low voltage. The highest current that could be

obtained was about 6 amp., and its voltage was about 1.3. Because of these facts, its use was limited to service requiring only small current drains.

DEVELOPMENT

The advent of the gasoline engine gave the development and production of the present type of dry cell a great stimulus. Its use in ignition systems demanded a cheap portable cell able to recuperate after comparatively heavy current drains. In 1897 its manufacture attained considerable volume. The present normal yearly requirements of this production include about 25,000 tons of high-grade manganese dioxide ore, an equal amount of carbon (petroleum coke and graphite) and 8,000 to 10,000 tons of sheet zinc together with corresponding quantities of zinc chloride, ammonium chloride, paper, carbon electrodes, pitch and sundry other substances.

METHOD OF MANUFACTURE

In the modern American dry cell of the usual type, the negative pole consists of a cylindrical zinc can which also serves the purpose of a container. Several sizes are on the market, the great majority, however, being about $2\frac{1}{2}$ in. in diameter by 6 in. high, (the so-called No. 6 cell). The inner surface of the zinc is lined with a special grade of absorbent paper, acting as a reservoir for the electrolyte, and has a diaphragm between the zinc and the positive pole. The depolarizing mass, called the "mix," is tightly tamped into the can around a centrally located carbon electrode to about 1 in. from the top. This "mix" is composed of ground carbon, usually calcined petroleum coke and graphite, manganese dioxide ore and the electrolyte. It, together with the carbon electrode, is the positive pole. After the mix has been tamped, the paper is turned down over the mix; sand or sawdust is poured in, to a depth of about $\frac{1}{2}$ in. and the cell is sealed with a hot pitch composition. The object of the layer of sand is to provide an expansion chamber for the electrolyte and the excess gas, and also to provide a dry bed for the hot pitch.

CONSTITUENTS USED

The zinc sheets used for the cans are substantially pure, prime Western spelter being generally used. The sheets are usually about 0.016 to 0.019 in. thick in the $2\frac{1}{2}$ by 6 in. cells. Comparatively little of the zinc is used up during the service life of a cell. The mechanical strength to withstand filling and the fact that the can corrodes unevenly, in spots, patches or streaks, must be taken into account when considering the necessary thickness. One of the problems of the dry cell manufacturer is to construct the cell so as to make this corrosion uniform.

Most manufacturers at the present time use a special grade of pulp board for lining the cans. Blotting paper was formerly largely used, but is now employed in only few brands. The paper now generally used consists only of ground wood pulp and sulphite pulp, and is 0.03 to 0.04 in. thick. It should be porous enough to allow the electrolyte to diffuse readily through it, but still retain the smallest particles of carbon and manganese; and it should be capable of absorbing several times its weight in water. Furthermore, it should obviously be free from metallic particles.

The depolarizing mass or "mix" is the vital part of the cell. Its different components must be suitably

*Part of a comprehensive bulletin on manganese that is to be issued by the Bureau of Mines.

proportioned to render the most efficient service. They, together with their different functions, will be discussed in turn.

The ammonium chloride should be equal in purity to the usual chemically pure article. It should be substantially free from alkalis, sulphates, inert material and heavy metals. When the cell is discharging, by virtue of the carbon, manganese dioxide, and zinc couple, the ammonium chloride is split up into hydrogen, ammonia, and chlorine, which attacks the zinc can, forming zinc chloride. The reaction is:

The liberated gases are the cause of polarization and will be discussed further, under zinc chloride and manganese.

The graphite used is generally of the artificial variety, several grades of which are prepared for use in dry cells. It does not enter into the chemistry of the cell, serving only with the coke to render the mix more conductive. The coke used is calcined petroleum coke, that is, residues remaining in petroleum stills. When raw, it is practically a non-conductor. However, on being calcined at a high temperature it becomes denser and as good a conductor as the better grades of amorphous natural graphite.

The relative fineness of the graphite, coke and manganese ore, together with their distribution, should be so uniform as to make the mix approach a solid porous mass. The current should flow along radial lines from the carbon electrode to every point on the surface of the mix adjacent to the paper lining. The ideal condition is to have each particle of manganese covered with a coating of carbon sufficient to render it a good conductor, but still porous enough to permit efficient depolarization, while the voids should be filled with the porous coke.

The zinc chloride should be of good grade, as free as possible from heavy metals. Its function is to depolarize the ammonia, which it does by the formation of double salts of zinc and ammonium chloride. No exact information is available as to the reactions involved, but it appears that a slightly soluble double chloride of zinc and ammonium is formed as the end product. During the earlier part of the service life of a cell, inefficient depolarization of the ammonia is probably often the cause of its failure under heavy drains. A cell that has been short-circuited or subjected to a heavy drain smells strongly ammoniacal when opened. Another cause of dry-cell failure is the formation of a highly resistant, non-porous crust between the paper lining and the zinc can, owing probably to the formation of the double salt mentioned above or the formation of zinc hydrate.

ROLE OF MANGANESE

The function of the manganese is to depolarize the hydrogen. The reaction involved is usually given as follows:

It has been shown that the manganese reacts almost instantaneously in depolarizing the hydrogen, very likely while the latter is still nascent.

CHARACTER OF MANGANESE ORE USED¹

Chemical Requirements. There are several factors entering into the suitability of manganese ore for dry

cells. It should have a high available oxygen content present in the form of pyrolusite (MnO_2), and a minimum amount of iron and should be free from copper, nickel, cobalt, arsenic, and other metals electronegative to zinc. Copper in particular is very harmful. If these impurities are present in the form of compounds insoluble in the electrolyte, they do no harm, other than being inert or poor conducting materials. If soluble, however, their solutions diffuse to the zinc can, where they are deposited, forming an electrocouple which results in local and useless corrosion of the zinc and consequent deterioration of the cell. When the cell is in service, the deleterious action of these impurities is greatly hastened.

Physical Requirements. The physical properties of manganese ores also influence their suitability for use in the dry cell. It is generally conceded that an ore should be somewhat porous to perform its function efficiently. A somewhat hard but porous ore is likely to give better results than a hard, dense ore, even though the latter is higher in available oxygen. In a dense ore, the depolarizing reaction takes place only on the surface, while in a porous ore it is able to occur throughout the mass. Better service life is obtained from a dry cell containing rather coarsely ground ore which is able to hold more electrolyte than finely ground ore. Other factors of importance are the porosity of the ore and the fact that more contact resistance exists between the particles of fine ore than those of coarse ore. It has also been demonstrated that careful grading of the ore greatly influences the performance of a cell. The ore, therefore, should not be of an earthy nature like wad, as this mineral does not lend itself to efficient milling and grading.

Prior to the war, the manganese ore used in dry cell manufacture was Caucasian pyrolusite. The common method of specification was for material containing from 80 to 85 per cent MnO_2 and less than 1 per cent iron. No particular attention was given to other ingredients, at least by most buyers, because of the purity and uniformity of the Caucasian ore. There are considerations other than the content of MnO_2 , which determine the usefulness of manganese for depolarizer purposes, such as the screen analysis, hardness, density and other physical qualities. Various manufacturers employ different specifications as to the screen analysis, a common specification being that the run of material shall pass through a 10-mesh or a 20-mesh screen. Some manufacturers specify the removal of the fine particles.

During the war manganese from many other sources was used in the dry-cell trade owing to the scarcity of the Caucasian material. Most of these ores run lower in MnO_2 and higher in iron and they have larger percentages of impurities, some of which are decidedly harmful. During the war, users accepted material that ran from 70 to 80 per cent MnO_2 , and as high as 3 to 4 per cent in iron. Users have found by experimental work and manipulation how to get results with domestic ores and with foreign ores other than Caucasian, closely approximating the results secured from Caucasian material.

An important source of manganese dioxide during the period of great scarcity during the war was the ore obtained from old dry cells, which was rejuvenated by processes generally kept secret by the firms employing them. Such processes doubtless contributed

¹Storey, O. W., "Determination of Manganese Dioxide in Pyrolusite," C. F. Burgess Laboratories, Madison, Wis.

in an important degree to the conservation of our high-grade domestic manganese ore.

In the manufacture of dry cells, two classes may be recognized—the standard or so-called No. 6 cell, which is used for ignition, telephone, signal and other similar purposes; and the small-size, or flashlight type, which is used for portable lighting. The quantity of pyrolusite ores used in the standard No. 6 cell is far larger than that used in other sizes. In the flashlight business, which is growing with great rapidity, the higher grades of materials are required, such as 80 to 85 per cent ore which has been purified and also various grades of chemically prepared manganese dioxide and hydrates of the same.

Manganese Ore in the Ceramic Industries

USE IN MAKING GLASS

Practically all the raw materials used in glass contain some iron, usually in the form of ferric oxide. The iron, when present even in small quantity, imparts to the glass a pale green color which increases rapidly in intensity as the iron content increases. If a colorless glass is desired, this green color must be removed, removal being effected by the use of various decolorizers. Manganese, selenium, cobalt and nickel are the most common decolorizers in use, and of these four, manganese has been most commonly employed because it permits easy control of the color. In using selenium and nickel, the quantity must be carefully controlled, but these latter substances are desirable, especially in window and plate glass, because glass decolorized with manganese often changes to a pink color on exposure to the light. A decreasing quantity of manganese is being used by makers of tank glass, and its place is being taken by selenium.

The quantity of manganese used varies considerably, depending on the character of the glass, the method of its manufacture, the iron content of the raw materials and the character of the manganese ore used. Each manufacturer has his own ideas on this subject and he puts these into practice within certain limitations. The quantity used is figured in terms of pounds of manganese dioxide per 1000 lb. of sand, which constitutes 50 to 75 per cent by weight of the entire batch. The temperature employed in the glass-making process is also a factor determining the quantity of manganese dioxide used; the higher the temperature employed, the more manganese is necessary owing to the volatilization. The maximum limit is 10 to 15 lb. of manganese dioxide per 1000 lb. of sand, from which it may range to as low as 2 to 2½ lb. of manganese dioxide.

CHEMISTRY OF USE OF MANGANESE IN GLASS MAKING PROCESS

The compounds of manganese, when other coloring ingredients are absent, produce pink, purple and violet hues according to the chemical nature of the glass. The presence of manganese dioxide neutralizes the green color due to the presence of iron compounds in the raw materials. Used in excess, it imparts an amethyst tint, and when used in considerable excess, the color is so intense as to appear black.

The neutralization of the iron tint by manganese dioxide is explained by some chemists on physical grounds, and by others on a purely chemical basis. The green tint is due to the presence of ferrous silicate. It is thought by some that this green compound is oxidized

to the ferric silicate, the color of which is an almost imperceptible pale straw yellow. According to this view, the oxidizing agent used must not completely decompose at high temperatures, and manganese dioxide appears to be the most available compound fulfilling this condition. At red heat, the dioxide loses one-third of its oxygen, leaving the tetra-oxide (Mn_2O_4) which, at still higher temperatures, is an oxidizing agent.

Red lead and other oxidizing agents have not this decolorizing power, which has given basis to the thought that the result is not due to oxidation, or chemical reaction, but that the phenomenon is purely physical in its nature. It is possible, however, that other compounds may lose their oxygen at too low temperatures to be effective as oxidizing agents.

SPECIFICATIONS FOR MANGANESE ORE USED IN MAKING GLASS

Before the war, the ordinary specifications for manganese ore used in glass making were 85 to 90 per cent manganese dioxide and less than 1 per cent metallic iron. Outside of these two ingredients, each manufacturer has his own peculiar requirements. Special glasses may require a grade of ore carrying more than 90 per cent manganese dioxide and less than 0.5 per cent iron. The higher the manganese content and the lower the iron, the better the material for glass-making purposes. In general, the grades of ore used in this industry are similar to the grades used in the dry cell industry. Obviously, siliceous pyrolusite is not objectionable, but carbonaceous pyrolusite is.

The manganese ore for use in glass is sold in powdered, granulated or lump form. There are certain objections to the lump form, owing to the time required to melt it into the batch. The powdered ore is used principally where the glass is made in pots. The lump ore, or granular, is used when melting is done in tanks.

Before the war, high-grade pyrolusite for glass making and other chemical purposes was imported from Russia, Saxony, Japan, Nova Scotia, and other foreign countries. As the war progressed, it became difficult to obtain foreign high-grade ore and, as a consequence, specifications were relaxed and low-grade ores were offered and purchased. During the war period some excellent domestic ore was developed, which found a ready market.

OTHER CERAMIC USES

Another use for manganese ore in the glass-making industry has developed in the last few years, namely, in the production of black glass used for ornamental purposes. About 3 per cent of ore is added to the batch in making this opaque glass. Pyrolusite is also added to the constituents of glazes and enamels to produce purple tints. Black enamels are those containing manganese. Manganese oxide is also used in brick making.

Use of Manganese Salts in Driers

Definition. Driers are those substances, generally metallic oxides or their compounds, which are added to linseed or other drying oils at high or low temperatures to make them capable of readily absorbing oxygen from the air, or of drying by its action. The action is considered by some chemists to be catalytic, the manganese compound acting as a catalyzer or carrier of oxygen. The principal manganese compounds used as driers are: Manganese sesquioxide (Mn_2O_3), pyrolusite (MnO_2), also known in the trade as dioxide, binoxide or peroxide,

manganese hydrate, sulphate, borate, resinate, linoleate, oxalate and possibly other salts. Certain corresponding double salts of manganese and lead are often used.

Some persons claim that pyrolusite is now little used in driers because the manufactured hydrate, on account of its purity, gives better results. This claim does not agree with statements made by dealers in the trade. Of the various substances named above, each acts in a way peculiar to itself. These driers are added only in small quantities, usually less than 0.5 per cent.

Manganese Dioxide. Manganese dioxide is extensively used as a drier. It comes onto the market in two forms, the natural and artificial. The natural mineral, pyrolusite, is simply ground to a powder with water and then dried. The mineral is essentially a peroxide, a class of substances containing more oxygen than is required to satisfy the valence of the metal present. This extra oxygen is loosely combined and readily enters into combination with oxidizable bodies. This feature in the composition of manganese compounds makes them useful in oil boiling, for the oxygen during this process combines with the oil, oxidizing it, while the manganese dissolves to some extent in the oil in the form of a compound with the linoleic acid of the oil. In consequence of this action manganese compounds are powerful driers. The quantity of manganese dioxide added in the process of boiling is small, not more than $\frac{1}{4}$ lb. to a hundredweight of oil to get the best results. The use of the black dioxide, however, tends to make the oil dark.

Manganese Sulphate. The methods of preparing this compound and its uses are described later. Rather less than $\frac{1}{4}$ lb. is added to each hundredweight of oil or paint. It is largely used by oil boilers as a drier of pale boiled oils.

Manganese Borate. Manganese borate is perhaps the least objectionable of all the manganese salts used as drying agents, though the black oxides are more largely used. To make the borate, 1 part of manganese sulphate is dissolved in 10 parts of distilled water and a little of this is added to some soda solution to determine whether any iron is present. If pure, the manganese sulphate solution is added to the hot borax solution as long as a precipitate forms. The precipitate is filtered, washed with hot water, and dried.

Manganese Resinate. Resinates, formed by the combination of resin or rosin with certain metallic oxides, occupy a prominent position in modern varnish and paint making and with the exception of the linoleates are most readily soluble in linseed oil. The manganese resinate is made as follows: Soda ash is dissolved in water and the solution is boiled with steam, and light coarsely powdered rosin is added. After the proper quantity of rosin has been added, more soda ash is added. The clear solution is allowed to run into a clear manganese chloride, the resinate separating as a white flocculent precipitate. This is filtered, washed and dried.

Manganese Linoleate. This is made by pouring a solution of a soap, made by boiling linseed oil and caustic soda, into a solution of manganese chloride or manganese sulphate. It forms a dark-brown plaster-like mass, liable to oxidation. When exposed to air, the surface becomes covered with a hard rather insoluble protective skin. The material should, therefore, be kept in tightly closed vessels. It acts both as a bleaching agent and a drier on linseed oil. One pound mixed first with 5 lb. of linseed oil and the whole poured into 10 gal. of linseed oil at 250 deg. F. gives a good drying oil.

Manganese Oxalate. This salt is prepared by precipitating manganese salts with oxalate of soda or potash or by treating manganese hydrate or carbonate with oxalic acid. One of its advantages is said to be that during the process of oil boiling it is decomposed, the manganese dissolving in the oil in combination with linoleic acid, while the oxalic acid is decomposed and evolved in the form of carbonic acid. One-fourth to one-half a pound may be used per hundredweight of oil.

Use of Manganese in Miscellaneous Chemicals

Manganese Chloride. Manganese chloride ($MnCl_2$) is prepared by the action of hydrochloric acid on the dioxide. Chlorine is a by-product of this reaction. It is a rose red, deliquescent salt used in dyeing cotton cloth a manganese brown or bronze. The fabric to be dyed is soaked in the salt solution and passed through a caustic alkali, whereby manganese hydroxide is precipitated in the fabric and on subsequent oxidation, turns brown. The material thus treated may also be used for subsequent dyeing by aniline black.

Manganese Sulphate. This salt ($MnSO_4$) may be prepared on a large scale from the black dioxide by heating to redness with ferrous sulphate and by subsequent extraction with water. It forms pink crystals which are readily soluble in water and are used in calico printing and in porcelain painting. It is also used as drier for pale oils or for conversion into the oxalate or borate which are used for the same purpose.

Manganese Persulphate. This salt, $Mn(SO_4)_2$, is prepared by the electrolytic oxidation of manganous sulphate ($MnSO_4$) and forms a black substance which can only be obtained in solution in the presence of sulphuric acid. It has marked oxidizing properties and is used as an oxidizing agent in making organic products.

Potassium Permanganate. This substance ($KMnO_4$) is prepared industrially by mixing a solution of caustic potash (KOH), specific gravity 1.44, with powdered manganese dioxide and an oxidizing agent like potassium chlorate. The whole is boiled and evaporated, and the residue is fused in crucibles and heated until it acquires a pasty consistency. The potassium manganate (K_2MnO_4) thus obtained is dissolved by boiling with much water while a current of chlorine, carbon dioxide or ozone is passed through the liquid. The potassium permanganate separates in crystalline form from concentrated solutions even in the presence of the caustic potash formed during the reaction, and is separated from the dissolved substances in a hydro-extractor.

The permanganate is used for conserving wood; it is also used for bleaching textile fibers, by immersing them for a time in an aqueous solution of the permanganate and then dissolving the manganese dioxide with sodium bisulphite. The permanganate is an energetic disinfecting and oxidizing agent and is used for purifying various gases.

Chemical Glassware

The manufacturers of chemical glassware in this country fear that the importation of the Japanese laboratory glassware will greatly endanger the American industry. It is claimed that labor alone costs in this country nearly equal the selling price of the Japanese goods. A committee of chemical glassware and porcelain manufacturers has urged the Ways and Means Committee of Congress to levy a 60 per cent *ad valorem* tariff on imports.

Exports and Imports

Consumption of Tungsten in 1918

An interesting summary of the consumption of tungsten in 1918 based on questionnaires distributed by the Bureau of Mines shows that the tungsten used in the making of tungsten powder, ferro and acid, from May to December, 1918, amounted to about 7,500,000 lb., from which it is estimated that the total tungsten used in such products for the calendar year 1918 amounted to about 10,000,000 lb. and that the amount of tungsten used in making malleable products during the same time was approximately 210,000 lb.

The quantity of high-speed steel made from May to December, 1918, was nearly 30,000,000 lb., from which it is estimated that the total weight of such steel in the year was somewhat in excess of 40,000,000 lb.; the tungsten content was probably nearly 7,000,000 lb. The tungsten steel made from May to December, 1918, was in excess of 45,000,000 lb., from which it is estimated that the total quantity produced in 1918 was approximately 62,000,000 lb.

The amount of 60 per cent concentrates required to make the tungsten powder, ferro and acid used in 1918 was approximately 13,000 tons, assuming that 1 ton of 60 per cent concentrates is reduced to 760 lb. of contained tungsten in ferro.

The accompanying diagram of manufacture of tungsten products gives a comprehensive survey of this field.

CHART SHOWING USES OF TUNGSTEN

Growth of the Kelp Organism

By J. W. TURRENTINE

EARLY surveys of the areas of growing kelp, made by the Bureau of Soils from the Santa Cruz Islands, on the coast of Lower California, to the Peninsula of Western Alaska, showed in the aggregate such enormous quantities of kelp available that it appeared that here was the source of potash which might be developed into an important industry. The early surveys had little reference to the accessibility of the growing kelp or to the feasibility of harvesting it for fertilizer purposes, since at that time, of course, no plants had been constructed for the treatment of kelp, and it was not possible to bring to bear any information obtained in actual experience. Now for several years kelp potash plants have been in operation, and we are beginning to know how to estimate with some reliability the quantities of potash that can be obtained from kelp in actual commercial operations; and while these quantities are relatively small as compared with the total quantities existing as growing kelp, they are still large enough to warrant us in the belief that it will be possible to establish a kelp potash industry that for normal times will be both permanent and important.

To furnish the annual tonnage recently cut in California with certainty (400,000 to 500,000 tons), practically the entire areas of growing kelp of southern California and the islands contiguous thereto from Point Conception southward have been required. It is entirely possible that, after greater experience in the gleanings of kelp and the conservation of the kelp beds, these areas can be made to furnish considerably more than this. At present the kelp beds are yielding three or four crops of kelp per year.

PROPER HARVESTING PROCEDURE

To obtain the maximum yields, the same procedure should be observed with regard to harvesting kelp that is observed with regard to harvesting any agricultural crop that is a perennial and renews itself promptly after harvesting. That is to say, sufficient time should be permitted to elapse for the growth to renew itself fully, otherwise only an imperfect yield is obtained. Now control of the kelp beds of California lies in the hands of the State Fish and Game Commission, who declare harvested areas closed to harvesters until the growth has renewed itself completely. This undoubtedly will result in a larger yield of kelp from each bed.

But with all this, a liberal margin must be allowed over the actual tonnage required to provide against unavoidable contingencies such as the destruction of a portion of the beds by storms or by disease, as happened during the summer of 1918 in some of the large beds in the Santa Barbara region. At the same time it is within the realm of possibility that areas of growing kelp can be enlarged by kelp farms, and that increased economy in harvesting, a larger number of crops per annum, and great improvements in the technology of the industry may all combine to bring about an enlargement of the industry here. And, besides, there are large areas of kelp on Puget Sound and in Alaska which to date are practically untouched, certainly some, and perhaps all, of which can be made to yield their quota of potash.

The kelp making up the beds of southern California is known botanically as *Macrocystis pyrifera*, and grows in about 75 ft. of water. Its place of growth is deter-

mined by a suitable bottom whereon it can secure anchorage, and tideways or surf to keep it supplied with fresh volumes of water from which it obtains its sustenance. It is held upright in the water by small air bulbs, pneumatocysts, one at the base of each leaf, which keep it pulled upward toward the light; and on reaching the surface it continues to grow, spreading out on the surface in large tangled mats. Its total length is probably from 100 to 150 ft.

HOW KELP IS GATHERED

With the cutting knives lowered into the water and cutting at depth of 6 ft., the harvester is forced through this mat of growing material and cuts it loose in quantities, dragging it on board by means of an apparatus similar to the familiar reaper of the grain harvester. It is then properly stored by means of a distributor operated mechanically, the entire apparatus making possible the harvesting of some 30 tons per hr., with a total crew of not more than five men, one in the engine room, one in the pilot house, one to man the cutter and its engine, and two to distribute the load. By this simple mechanism it is possible to handle tremendous quantities of material, and the problem of harvesting would be very simple indeed, if it were not for the long hauls occasioned at times by the distance of plants from the kelp beds, and the seasons of storms which interfere with harvesting.

The opinion has been expressed by operators of kelp harvesters that the kelp after having been harvested comes back in thicker growths, from which it has been concluded that there is a sort of stooling effect as in the case of alfalfa or wheat. The lack of definite knowledge as to what actually takes place at the bottom of the ocean, 75 ft. below the surface, makes it impossible to say whether this is a true statement of what actually takes place or not. But at least it is indicative of the completeness with which the kelp beds restore themselves after being cut over. It appears probable that when the growing tip on the end of a strand of kelp is cut off, that strand dies back to the bottom, and that the prompt regrowth is the result of what might be termed as undergrowth of shorter kelp shoots which spring to the surface promptly when the sunlight is admitted to them through the removal of the dense mass of kelp lying on the surface. When the so-called kelp roots, or, more properly, hold-fasts, are washed ashore, it is seen that there has been an actual branching; and it is quite possible that branching at the bottom is induced by cutting off the surface growth.

INVESTIGATIONS IN PROGRESS

Investigations are now in progress touching on all of these questions. They are purely biological and may be termed mariculture. Some day we may have developed a definite science, or a science as definite as that of agriculture, pertaining to the growing of such things in the sea. Of course, the cultivation of seaweeds is an old-established industry of Japan. There the developments within the past few years, or since the Russo-Japanese war, have resulted in the establishment of a kelp potash industry which has made possible the production of potash and iodine there in quantities adequate to supply domestic needs in these two commodities and to make possible their exportation in certain quantities.

This is astonishing, indeed, when we remember that the kelp there dealt with grows at the bottom of the ocean and is only a few feet in length. It is gathered

at a depth of some 15 ft. almost altogether by woman divers, who go overboard with a knife, gather a bunch in their arms, cut it off, and come back to the surface with the bundle. If this can be done by the Japanese, it is evident that by the exercise of the proper science and economy we in this country, who have kept growing in such a manner that it can be harvested in hundred ton lots by machinery, can likewise establish an industry of importance and value.

Fibrous Structure in High Carbon Steel

BY A. W. LORENZ

MUCH discussion has been aroused recently regarding the cause of the so-called "fibrous" or "woody" structure in high carbon and nickel steel forgings. This trouble seems to have manifested itself strongly in the manufacture of ordnance material. In this connection the writer wishes to present some interesting facts and data in connection with one ordnance contract in particular, which may throw some light on the general question of fibrous structure.

THE SPECIFICATIONS

The specifications required that a slab or test slice be cut from one end of the forging, which was approximately 9 ft. long and had a diameter of about 7 in. Out of this slice five transverse tests were required: Bend test A, tensile test 1, tensile test 2, tensile test 3, bend test B.

The actual test requirements need not be stated, as their consideration is unnecessary in this article. It is sufficient to state that the failure of any one of the above tests called for retreatment or rejection of the forging. Two forgings were made from one ingot, and it was the practice to cut the test slabs from the two forgings off the particular ends which represented the top and bottom of the original ingot. If a re-test was required it was then made from the end of the forging corresponding to the middle of the original ingot.

RESULTS

A tabulation of the results from about 700 tests gave:

	Top Per Cent Good	Middle Per Cent Good	Bottom Per Cent Good
Test No. 1.....	92	90	96
Test No. 2.....	43	31	82
Test No. 3.....	62	71	75

It will be noticed that No. 1 test (tensile) was invariably good. The probable reason for this will be discussed later. However, the outstanding feature of the above tabulation is the greater uniformity of the three tensile tests taken from the slice representing the bottom of the ingot, and the marked superiority of the results off the bottom slice as compared with the tests from the middle and top of the ingot. In fact, this superiority became so evident that the Government, to protect itself, later ruled that all tests should be taken from the top and middle positions. This at once suggests that the trouble, which generally manifested itself by fibrous fracture, is due to impurities of some nature which slowly arose to the upper portions of the ingots while cooling, leaving the bottom relatively clean. Several heats were therefore made, using the utmost care in the control of furnace conditions looking toward the

production of steel free from impurities. These heats were no better (in fact one was worse) than the average.

ACCIDENT LEADS TO INTERESTING DEVELOPMENT

About this time an accidental oversight in the shop led to interesting developments. It was the practice to wash the ingot molds with tar in order to prevent surface cracks. On one heat this was overlooked, and the resulting forgings were 100 per cent good. This recalled to the writer the fact that the first two sample heats were also extremely good and that the only difference between these and subsequent heats was the use of clay wash instead of tar on the molds. In connection with this trend of thought it was noticed, while pouring several heats of metal into tar-washed molds without the addition of aluminum, that the metal boiled out until a cone over a foot high was formed at the top of the ingot, whereas with clay or graphite washed molds, the metal remained quiet.

Now it seems to the writer that the tar, in distilling, filled the otherwise good metal with gas which worked its way to the upper portion of the ingot, there to be entrapped by the freezing metal. This accounts for the superiority of the tests from the bottom end of the ingot. On forging, these blow-holes were forged out but not welded shut and consequently hairline cracks were developed which would have little effect on a longitudinal test but were quite detrimental to transverse tests. Of course slag and solid impurities would act in the same way, but microscopic and macroscopic examination of the fracture would disclose the presence of slag. Slag was certainly present, but not in undue amounts, and no more so in bad than in good samples. Moreover, oxidizing slag would be evidenced by a decarbonized zone under microscopic examination, and in the fracture itself perhaps by a discoloration.

This was not the case with the failures in question. A gray fibrous structure was evident in the fracture usually, and in well marked samples the break seemed worn with a smooth, silvery appearance usually associated with the inside of a blow-hole that has not been exposed to oxidation. Examination of unetched samples showed, under a magnification of 100, the presence of numerous pin-holes, so small as to be quite invisible at 100 magnifications after etching for grain structure. On treating the unetched samples with iodine, these small pin-holes gradually developed into cracks about $\frac{1}{8}$ in. long in the direction of forging. Etching with hot sulphuric acid developed this structure still more strongly, showing cracks sometimes $\frac{1}{4}$ in. in length.

THEORY AS TO THE NATURE OF THE DEFECT AND WHAT MAY BE ITS CAUSE

As a general rule slag inclusions should possess a more appreciable thickness than was shown in the specimens mentioned above. The nature of the defect, therefore, seems to be a fine crack of no appreciable thickness, resulting as stated before from the squeezing shut of a blow-hole without actually welding it together. It will be noted in this respect that tensile tests No. 1 were invariably good, which may be explained by the fact that this test was in the region of greatest pressure during working under the press, and the blow-holes at this point may have been welded together to some extent. It may be stated that the forgings, being

irregular in cross-section, were formed in a die, so that the pressure was always applied over test No. 1. On the other hand, the middle tests were responsible for the greatest number of failures and it is easy to believe that the center of the forging did not receive sufficient work to weld the holes at this point. On making a macroscopic examination of a slice adjacent to a test slice, after etching with hot sulphuric acid for about half an hour, it was found that whenever the center of the slab was sound, the central test would pass specifications, and when the center was badly pitted, the test would fail.

CHANGE IN MOLD WASH

Fourteen heats were cast using graphite as a mold wash instead of tar. The results were not nearly as satisfactory as expected, but were so much superior to the results on steel from tar-washed molds as to justify the statement that gassing was the cause of the trouble. The following percentages are based on all tests (to the number of several hundred) made after the change in method of testing which called for all tests to come from the top and middle:

Percentage of sets good (all three tensile tests fine):

Graphite wash, 68 per cent.

Tar wash, 34 per cent.

	Test 1, Per Cent	Test 2, Per Cent	Test 3, Per Cent
Graphite wash (good)	100	72	95
Tar wash (good)	91	37	66

In justice to the manufacturer, it should be noted that these figures do not refer to the ultimate percentages of accepted forgings.

EFFECT OF ADDITION OF ALUMINUM

It may be stated that little or no aluminum (not more than $\frac{1}{2}$ oz. per ton of steel) was added to the steel (basic open hearth) after the use of graphite wash was resorted to. It is probable that the addition of a larger amount of aluminum or other scavenger would have resulted in still more improvement, but suspension of the contract shortly after the armistice was declared prevented further experimenting along this line. The above data would seem to indicate that fibrous structure is often due to the presence of gas cavities which during working have been squeezed out to a thin streak, without, however, being completely welded.

While the use of tar has been held responsible for the trouble alluded to in this particular instance, it is not the writer's intention to lay the blame for all fibrous or woody structure on the use of tar as a mold wash. It is well understood that some manufacturers may have found a way of using tar without encountering difficulty. It is also understood that any practice conducive to the formation of cavities and gas pockets will tend toward the formation of a fibrous structure during forging, provided the work is insufficient to completely weld the cavities together.

Importation of Tin

The War Trade Board Section of the Department of State will now issue licenses permitting the importation, on or after Sept. 1, 1919, of pig tin and all metal alloys containing tin, including tin drosses, tin oxides, solder drosses, type metals, anti-friction metals, waste metals and other metals containing tin, from points other than points of origin and without reference to the date of shipment.

Small Air Compressors

AT THE outbreak of the war, there was an urgent demand for a large number of small air compressors for military service where reliability was imperative. The small Imperial Fourteen type manufactured by Ingersoll-Rand had but recently been tested out. The field performance of these machines has been pronounced satisfactory and they are now being placed on the market. There are four sizes, and the capacity range runs from 3 to 45 cu.ft. per min. at pressures to 100 lb. per sq.in. The compressors can, however, be used for pressure requirements up to 200 lb. per sq.in., the horsepower needed being, of course, increased. They are single acting machines of the vertical type built for belt drive. Where driven from line shaft, tight and loose pulleys are supplied; where the use of an independent motor is planned, they are ordinarily furnished as a

ONE TYPE OF A SMALL AIR COMPRESSOR

unit complete with motor, endless belt and short drive attachment. In the latter case a hardwood base plate is included with the standard equipment.

The machines are so well balanced as to operate satisfactorily if bolted to any solid flooring, but where permanency of installation is desired the building of a concrete foundation is advocated. The smallest size is built with ribbed cylinder for air cooling where the service is intermittent and with water cooled cylinder of the reservoir type for continuous operation. Larger machines are water cooled only, employing the reservoir jacket system except that, in the case of the largest size, a closed jacket for connection to pressure system is optional. In this connection it is worth noting that the reservoir cylinder design affords unusually ample water capacity and that both cylinder barrel and head are cooled. The manufacturer states that one filling of the water space will suffice for a 10 hour day's run.

In general design these compressors remind one strongly of an automobile engine. There is the same drop forged crank shaft and connecting rod, the die cast renewable bearings, the automatic splash lubrication system and general ruggedness and simplicity which have come to be recognized as guarantees of satisfactory service under all sorts of operating conditions.

It is pointed out, however, that these little units were designed to meet exacting efficiency tests and that, while simplicity was sought, efficiency was the outstanding requirement.

Vertical-Cylindrical Electric Furnaces for Heat-Treating and Shrinking

By A. M. CLARK

DEMANDS made by the United States Government during the war period for the speeding up of ordnance manufacture caused remarkable improvements in electrical furnaces, which it is predicted will have a far-reaching influence on the commercial use of industrial heating in the future.

Both the Army and Navy Departments, faced with the necessity of manufacturing guns in great quantity and at short notice, turned to the electrical engineer to help them solve their problems.

The result was the development by the General Electric Co. of a new type of electrical resistance furnace used with success in heat-treating gun forgings and in shrinking the jackets on gun barrels of large caliber.

Two forms of furnace were developed—a high-temperature resistance furnace creating a temperature of 1800 deg. F., used in tempering, hardening, and gun forgings; and a low-temperature furnace up to 950 deg. F., used primarily for shrinking jackets over gun barrels and applicable to other practices, including shrinking collars on crank shafts and rims on wheels.

This type of shrinking furnace is constructed in sections and has been built up to a depth of 88 feet. The best example is installed in the Washington Navy Yard, where guns of large caliber were built during the war. The furnace is of the vertical-cylindrical type sunk into the ground to the required depth, a section of which is shown in Fig. 1.

Its internal construction is shown in Fig. 2. Furnaces consisting of more than one section are usually equipped with a hand control which permits bringing the charge up to temperature at a uniform rate throughout the length of the furnace, the maximum temperature used being approximately 950 deg. F.

When a one-section furnace is used, it is ordinarily provided with automatic control. Furnaces of more than one section are usually hand-controlled, but automatic control can be provided. A complete one-section furnace consists of a cylindrical section, cover, base and work

FIG. 1. SHRINKING FURNACE, ONE SECTION, WITH COVER

FIG. 2. INTERNAL CONSTRUCTION DIAMETER INSIDE BORE, 4 FT.

base. The cylindrical section consists of top and bottom castings with supports, inner and outer casings enclosing the insulating material, and heating units and guards. The cast rings which form the ends of the section are recessed in such a manner that the sections can be stacked one above the other, which permits constructing a furnace of any desired height from standard sections. Provision is made for the unequal expansion of the inner and outer casings due to difference in temperatures. There is a minimum of through metal from the inner casing to the outer casing, hence the heat losses are reduced to a minimum.

The heating unit consists of a calorite ribbon mounted on a cast iron supporting plate, and insulated therefrom by suitable refractory material. A number of units are connected in series depending upon the voltage of the power supply. All connections are made with flat steel bus bars, as experience has demonstrated that the best connections can be made between flat surfaces, and steel will not oxidize at the temperatures employed in these furnaces.

The construction of the vertical-cylindrical high-temperature heat-treating furnaces involves the use of a heavy calorite ribbon supported on the inner walls of the furnace. The furnace is divided into a number of separate heating zones with an automatic temperature control for each. As indicated in Fig. 3, the walls consist of an inner lining of refractory brick and insulators backed up by a double course of heat-insulating brick and protected by a sheet metal casing. The ribbon supports and insulators are both of molded special compound laid in the lining of refractory brick with a spacing block of the same material placed between the insulators of adjacent windings, or zones. The insulators, spacers and spacing blocks are fitted at the back into a steel channel (*H*) which is in the form of a ring made up of a number of sectors tied together by bolted clamps, not shown in this figure. The spacing block (*A*) acts as a protecting buffer for the ribbon support insulators and any blow is transmitted to and distributed by the channel (*H*). An opening is provided in the spacing block (*A*) for the charge pyrometer tube, with a similar

FIG. 3. SECTIONAL VIEW, SHOWING CONSTRUCTION OF WALLS AND REFRACTORIES CONVEYING HEATING RIBBONS

opening for the ribbon pyrometer in the support insulator at (D). The ribbon is welded to the terminal stud (E) and adjacent lengths of ribbon are joined by welding to the splice piece (J). It will be noted that the ribbon insulators are protected from mechanical injury by the spacing blocks and the shape of the former is such that any scale or dirt cannot accumulate and cause short-circuiting of the ribbon winding but will fall to the bottom of the furnace. The ribbon insulators being imbedded and forming a part of the furnace wall hold the ribbon firmly in place and eliminate the need of any form of metallic support with the inherent weakness of the latter at high temperatures. Furthermore, the omission of all metal, except through ribbon windings, in-

HEAT-TREATING GUN FORGINGS IN THE ELECTRICAL FURNACE

sures quick heating of the furnace and reduces to a minimum the waste of energy due to heat storage.

Each section is provided with a control panel, and is controlled independently of the other sections. This is accomplished by very accurate and sensitive automatic controlling instruments, one for each section, operating in conjunction with suitable relays and a contractor, so that when the temperature reaches the value for which

the instrument is set, the relays and contractor are operated to disconnect the section from the power line. When the temperature has fallen only a few degrees the relays and contractors are operated in the reverse order, again connecting the section to the line. Fig. 4 shows the control instrument, and Fig. 5 shows a control

FIG. 4. TEMPERATURE RECORDER CONTROLLER FOR CONTROLLING TEMPERATURE AT TWO POINTS

board for a group of furnaces, with the instruments on the sub-base.

The instrument may be set to hold any desired temperature, and is provided with a paper roll and recording mechanism, so that indicating, recording and controlling features are all combined in a single instrument, and charts are available for record and reference.

The temperatures are measured by means of thermocouples, which experience and research have developed into exceedingly accurate and reliable devices. Two of these thermocouples are used in each furnace section, one near the resistor, and the other against the charge.

FIG. 5. AUTOMATIC PANELS AND CONTROL INSTRUMENTS

Probably the largest installation of this apparatus is in the plant of the Tioga Steel & Iron Co. of Philadelphia, Pa., a concern taken over by the Government for the war and engaged almost wholly in naval ordnance activity.

With cessation of hostilities and the practical abandonment of munition work, engineers are turning their attention to the use to which these furnaces can be put in industrial work. There are a large number of heat-treating processes in the manufacturing industries requiring temperatures from 900 to 1800 deg. F. Chief among these may be mentioned drawing and annealing carbon steels, drawing high-speed steels, annealing brass

and copper, and baking vitreous enamels. The disadvantages of electrically-heated furnaces constructed and equipped with heating units and temperature-control systems as described are automatic control of the temperature, minimum temperature variation in the furnace, maximum rate of heating the charge, uniform heating throughout the charge, maximum efficiency in heat treating, elimination of scale due to oxidation, duplicate results day after day, and elimination of combustion methods with their attendant uncertainty of results and general fuel problems.

General Electric Co.,
Schenectady, N. Y.

Pipe Line Strainer

The G.R. duplex strainer has been especially designed for installation in the suction or discharge lines of lubricating or fuel oil systems for the removal of solid foreign material in suspension. Such foreign material, if not removed, makes the lubrication inefficient and may seriously damage bearing surfaces. Similarly, sedi-

PIPE LINE STRAINER

ment in fuel oil tends to clog the burners, reducing their capacity and necessitating frequent cleaning.

This strainer is also suitable for straining the water supply from such sources as rivers and lakes to prevent weeds, sticks, marine plants and small fish from entering the pipe lines.

The strainer consists of a cast-iron body containing two perforated steel or brass baskets. The valve arrangement permits of the complete removal and cleaning of either basket while the other remains in service.

In operation the oil or other liquid enters the inlet connection of the strainer and passes into whichever basket is in service. The solid matter remains in the basket, the clean liquid passing through the perforations and thence out of the strainer.

All cast-iron sections are cylindrical, resulting in maximum strength. The valve mechanism is very simple and the valves are easily re-ground. This apparatus is described in Bulletin 1150 published by the manufacturer, the Griscom-Russell Co., 90 West St., New York City.

Sixty-Inch Gyrotory Crusher

Steam shovel dippers and gyrotory crushers have been trying to outgrow each other for forty years. Half-yard, yard, two-yard and five-yard dippers have had their counterparts in 7, 15, 36, 42 and finally 60-in. intake gyrotory crushers. The latest achievement is

the giant "Bulldog" having two intakes, 190-in. annular segments 60 in. wide, and an output of 2500 tons per hour. The Traylor Engineering & Mfg. Co., of Allentown, Pa., built this 60,000 tons per day world's record machine on special order in 3½ months. The dimensions and weight of the principal parts are:

Height	17 ft. 8 in.
Diameter	19 ft. 6 in.
Shaft length	21 ft.
Shaft diameter	15 ft.
Receiving openings	15 ft. 10 in.
Pulley	7 ft.
Eccentricity	2 in.
Shaft	28 tons
Shaft bearings, etc.	34 tons
Head	30 tons
Top shell (2 pieces)	54 tons
Middle shell	50 tons
Bottom shell	47½ tons
Bottom shell lining	5 tons
Spider	30 tons
Complete crusher	278½ tons

The capacity with limestone reduced to 8 to 9 in. is from 2500 to 3000 tons per hr. The power required is 75 hp. with light running to 350 hp. with full load. The rate of running is 240 r.p.m. About 9 bbl. of lubricating oil is used in the system and is pumped continuously through the eccentric bearings, etc. Patents are applied for, Messrs. Richard Bernhard and L. J. Hewes being the engineers in charge of the development.

New Tube Mill Lining

Metallurgists will be interested in the description and illustration of a new tube-mill lining developed by F. B. Kilbourn of Montreal and manufactured by Burnett & Crampton, Rigaud, Quebec, Canada. As shown in the illustrations it consists of a series of chilled iron T-bars set on edge and spaced from three-

DETAIL OF TUBE MILL LINING

SHOWING CORRUGATED SURFACE DEVELOPED
DURING USE

quarter inch to one inch apart. The volume between the bars is filled with a rich cement grout, and when this is set the tube mill is ready for operation. After a few hours' running the concrete is somewhat worn, leaving the bars protruding and giving a corrugated surface which effectually lifts the contents of the mill. It is reported that the mill, as shown in the illustration, suffered a wear of only one-eighth inch after 5000 hours of operation. It is reported also that the wear is uniform.

Synopsis of Recent Chemical and Metallurgical Literature

Progress in Japanese Chemical Industries — Mr. Michel Annebault has given in the December, 1918, issue of *Chimie et Industrie* quite a lengthy description of the economic evolution of modern Japan, of which the following is a succinct abstract.

In 1858 the total Japanese foreign commerce, export and import, amounted to about \$13,560,000; in 1894 it was about \$119,195,000; in 1904 about \$156,635,000, and in 1916 it reached about \$435,153,000.

During 1916 the figures for export and import trading with the principal countries were:

Exports to:	About	Imports from	About
France.....	\$33,066,000	France.....	\$2,134,000
China.....	99,556,000	Germany.....	2,139,000
British India.....	36,998,000	China.....	56,123,000
United States.....	175,770,000	British India.....	92,712,000
Great Britain.....	53,030,000	United States.....	105,428,000
		Great Britain.....	42,237,000
Total.....	\$398,420,000	Total.....	\$300,793,000

The main products exported and imported were:

	Exports	Import
	About	About
Sugar.....	\$9,005,000	\$9,368,000
Pharmaceuticals.....	20,516,000	28,635,000
Dyes.....	4,382,000	4,382,000
Oil and fats.....	10,186,000	8,982,000
Paper (raw materials).....	7,419,000	8,395,000
Iron and metals.....	74,550,000	8,376,000
Manufactured metals.....	8,572,000	5,510,000
Machinery.....	18,052,000	16,166,000

The cheap labor conditions in Japan greatly favor her industrial development. Thus, for example, official figures for 1906 gave as labor wages per day: Carpenter about 45c, printer about 26c, tailor about 23c; in match factories women were paid 3c per day to label match boxes. A noteworthy remark is that in 1904 out of 558,041 persons employed in industrial factories 313,001

were women. The very efficient propaganda that "Japan must break foreign competition, otherwise she will be lost," is contributing more than anything else to keep the standard of wages so very low.

In 1914 the chemical industry in Japan was practically embryonic, but now the Japanese not only manufacture most of the chemicals needed for the rapidly increasing local consumption, but they also export a great number of them. To mention only a few:

Potassium Chlorate—Previous to the war potassium chlorate was imported mainly from Germany; but since importation was forcibly stopped plants have been installed for the treatment of seaweed, and now the Japanese can produce 10,000 tons of potash annually, and have even become exporters of potassium chlorate to the United States. Progress is now being made toward the large-scale manufacture of potassium cyanide.

Phosphorus—Practically all the phosphorus needed in pre-war times was imported from Europe; now the local production is amply sufficient for the increased needs.

Matches—The rapid development of the industries of phosphorus and potassium chlorate is intimately connected with the progress of the Japanese match industry. Japan is now one of the world's principal purveyors of matches.

Iodine—The treatment of seaweed for iodine at Hokkaido, Kanagawa, Chiba and Fukuoka is very successful. Japan is now a big exporter of iodine and potassium iodide.

Sulphuric Acid—Japan produces now about 3000 tons of 52 deg. B. sulphuric acid per day, and exportation is rapidly increasing.

Gas Plants—In 1870 there was only one gas plant in all Japan, located at Yokohama. Now there are about 120 plants manufacturing mainly coal gas and the by-products, ammonium sulphate, benzol, cresol, naphthalene, phenol, anthracene and other tar derivatives. Ammonium sulphate is also manufactured in electrochemical

TOTAL JAPANESE FOREIGN COMMERCE—IMPORT
AND EXPORT

plants for the fixation of atmospheric nitrogen. Phenol is manufactured synthetically, mainly at the Osaka Dye Works.

Artificial Fertilizers—In 1887 the first artificial fertilizer plant was installed at Kamayabari, but this industry progressed slowly, due to the fact that the Japanese relied mostly on natural fertilizers. With the increased agricultural demand the production of artificial fertilizers has progressed proportionately, and now it is one of the well-established industries.

Artificial Dyes—The industry of artificial dyes, which

was practically nil before the war, is now represented by 89 factories, and the life of this industry is more or less insured by government protective laws.

Pharmaceuticals—In 1884 there was in Japan one plant for the manufacture of pharmaceuticals, and this one needed government help for its upkeep. Now there is a number of successful plants, and they are already practically independent of foreign import.

Oils and Fats—The production of oils and fats reaches now about \$13,950,000, and this has contributed to the development of the industrials of soap (about \$4,443,000), candles, (about \$2,377,000), fatty acids and glycerine (about \$2,584,000), etc.

Paints, Gum Lacs and Varnishes—These industries started in 1887 with a small plant (the Nippon Paints Co.), and it had a hard struggle up to the time of the war. Now there are many plants with a production worth about \$1,550,000, and the demand is on the increase.

Rubber—The first plant in Japan was founded in 1887 at Asakusa. At the present time there are nearly 100 plants, and they are able to export rubber and rubber products. Japan's exportations of rubber tires alone amount to about \$2,100,000.

Ceramics—The crockery and porcelain industry is very old, but it was not until 1868 that Occidental processes of manufacture were introduced. Since then the total production has increased to more than \$9,000,000.

Enameled Ware—Previous to the war all the enameled metal-ware had to be imported from Europe; now the local industry supplies all the nation's needs and exportations amounting to about \$1,035,000 are made to Australia and China.

Glass—Starting with a small plant in 1871, the glass industry has grown until glass of different qualities is exported to the amount of about \$5,170,000.

Cement—In 1880 the first cement plant was installed in the Department of Yamagushi. This plant's production has increased tenfold (about 4,000,000 tons), and there are now 20 other plants, mostly in the Departments of Tokio and Orsake.

Paper—Occidental methods for the manufacture of paper were introduced in 1868. At the present time there are a great number of paper factories, which, besides producing the 225,600 tons of common printing paper for local use, also export to China and India about \$8,800,000 worth. The manufacture of the special Japanese paper has also increased since the introduction of machinery, and production has reached about \$10,600,000 worth and is still increasing.

Plastic Materials—This is a very recent industry in Japan, although practically all the camphor, which is one of the main raw materials, comes from Japan.¹ The first celluloid plant was installed after the Russo-Japanese war. There are now 12 plants, producing annually 2700 tons of celluloid, and celluloid is exported to Europe and America.

Sugar—Although the first beet sugar factory was put in operation in 1881 only a negligible quantity was produced up to the time when Japan came into possession of the Island of Formosa, which is a great producer

of sugar beets. The industry has progressed to such an extent that in 1916 Japan practically supplied her own needs and now she can even export sugar.

Electrochemistry—Japan has taken up and greatly developed this industry, and besides the electrochemically manufactured products already mentioned, she produces now on a large scale carbides, artificial graphite, metallic sodium, caustic soda, sodium chlorate, nitric acid, chlorine and many other chemicals.

In viewing the progress made by Japan in the main chemical industries it becomes evident that she has directed her mental and monetary resources to the manufacture of the products she imported in pre-war times mainly from Germany, and that she has succeeded in emancipating herself to such an extent that she will become Germany's successful competitor in the foreign markets.

Recent Chemical and Metallurgical Patents

Complete specifications of any of the United States patents abstracted herein may be obtained by remitting 5c. each to the Commissioner of Patents, Washington, D. C.

Calcium Bisulphite—In order to produce calcium bisulphite continuously, ALBERT G. HINZKE of Toronto has designed an apparatus in which the counter-current flow of lime water and sulphur dioxide may be reversed at will, thus preventing the formation of incrustations which tend to clog the openings in the absorbing system. Fig. 1 shows the apparatus in

FIG. 1. CROSS-SECTION OF ABSORBER

vertical cross-section. The four compartments are lined with acid-resisting material and are provided with a number of perforated splashboards. Assuming that the sulphur dioxide enters at the left, its course is indicated by the arrows. In this case the lime water is introduced through the central pipe in the top of the right hand chamber and is circulated progressively through the other compartments. The

FIG. 2. CIRCULATING SYSTEM

circulating system is shown more clearly in Fig. 2. A flow-box is interposed between each two compartments and the corresponding pumps. This box is divided by partitions in such a manner that, while a constant circulation is maintained through the sprayers in each chamber, there is also a movement of liquid from chamber to chamber toward the end at which the gas enters. Here the saturated solution is drawn off continuously to a storage tank. (1,303,314; assigned, by mesne assignment, to Ainswell G. McIntyre; May 13, 1919.)

¹EDITOR'S NOTE.—The output of camphor in 1917 was about 10,000,000 kin (a kin is 1.325 lb.), of which 70 per cent was produced in Formosa and 30 per cent was supplied by domestic producers. But since the wartime the output has gradually decreased on account of rise of wage. Last year's output was only 8,000,000 kin. This year's production is estimated to be still less, viz., 6,000,000 kin. Nowadays about 12,000,000 kin is annually demanded by celluloid makers, while camphor culture is too slow to meet this demand. This shortage of material will be supplied only by the foreign producer.

Electrodes for Caustic Cells.—CLARENCE W. MARSH of New York City has patented an improved construction of electrodes for cells engaged in the manufacture of chlorine or caustic alkali, one application of which is shown in Fig. 3. As the old anodes wear out they are replaced by those of sectional type (5); at the same time the flat perforated cathodes are replaced by bent plates (8) so shaped that the distance between electrodes is approximately constant. The great advantage of this style is that gases which form on the anodes in rising to the surface strike the under side of the section immediately above and are deflected into the inactive center part of the cell. In this way is provided an increased resistance of the upper part of the cell due to excess gas in the electrolyte, and better circulation is maintained. Step-construction of cathode increases the support for diaphragm (12), which may be correspondingly reduced in thickness with an attendant lowering of electrical resistance. Altogether, this construction reduces the necessary impressed voltage by 0.5 volt. (1,302,824; May 6, 1919.)

FIG. 3. ELECTRODE

Electric Furnace. — O. A. COLBY and FRANK THORNTON, JR., of Pittsburgh, Pa., have patented an electric furnace with protected electrodes (20) and a compound resistor capable of continuous operation at high temperatures. When the furnace, such as shown in Fig. 4, is held at about 1000 deg. C., the hottest portion of the carbon resistor is nearly 2000 deg. C., due to the negative temperature resistance of carbon. Now in order to prevent the hearth foundation (12) from being overheated despite the special refractory (18) the resistor is sectionalized to have a lower layer of high resistance material, thus carrying a lesser amount of current. Various combinations are suggested, such as a layer of crushed graphite (16) above, renewable through side hoppers, and underlain by crushed charcoal (17). Or the crushed graphite may

FIG. 4. ELECTRIC RESISTANCE FURNACE

form the lower layer and the furnace hearth itself consist of carborundum brick. The same construction reversed will form a chamber heated from both top and bottom. Or, wedge-shaped rods of carborundum,

graphite or amorphous carbon may be buried in the upper part of a crushed graphite layer. A further expedient to prevent overheating of the hearth refractories consists of providing a pre-heating chamber in the foundation brickwork (12). (1,306,250-251-289; assigned to Westinghouse E. & M. Co.; June 10, 1919.)

Disintegrating Metals.—E. J. HALL of New York City patents a method for disintegrating metals; in which molten metal drops in a fine stream through an atmosphere of inert gas into a circulating bath of cold liquid which does not react with the metal in any way. In this way chilled particles of pure metal are available for further grinding under inert oil to produce particles of the required size. (1,306,060; assigned to Metals Disintegrating Co.; June 10, 1919.)

Electric Furnace.—IVAR RENNERT of Djursholm, Sweden, has patented a furnace, shown in Fig. 5, wherein electrodes (1) project through a movable roof (2) and make contact with renewable granular carbonaceous material held on shelves at the side walls. The brickwork of the furnace is here protected from excessive heat by a thick lining of magnesite or carbon bricks (7). Various shapes of furnaces can be adapted to polyphase current, connected either in star or delta, to hold one or more shallow crucibles (4) for melting glass or metals, or the furnace may be made into a hearth. Residue from the combustion of electrodes is

FIG. 5. ELECTRIC FURNACE WITH MOVABLE ROOF

by this construction kept from contaminating the bath, and a strong and uniform heat had by the electrode arrangement and by reverberation from the furnace walls (1,305,167; May 27, 1919.)

Alloy for Glass Molds.—An alloy consisting of copper, 56-64 per cent; nickel, 13-17 per cent; zinc, 10-15 per cent; iron, 10-15 per cent, resists oxidization at high temperatures. In addition, it can be machined easily, so that it is especially suitable for the manufacture of glass molds. (1,310,363; FOSTER MILLIKEN of Lawrence, N. Y.; July 15, 1919.)

Deborating Chile Saltpeter.—ROBERT P. CALVERT and OTHO L. THOMAS of Wilmington, Del., have devised a novel method for removing borates from crude saltpeter or the refining by-product known as the potash crystal fraction, which contains from 20 to 50 per cent potassium nitrate and from 3 to 7 per cent boric acid, etc. Sufficient mineral acid is added to liberate all the boric acid, the salts are evaporated to dryness, methyl alcohol added and methyl borate distilled off in

the presence of a dehydrating agent. The ester is hydrolyzed, freeing the boric acid and converting the alcohol back for another cycle. Since borax is a very injurious impurity in all the uses to which caliche salts

are applied, such as fertilizer, black powder, etc., this process should prove to be important. (1,308,576-7; assigned to E. I. du Pont de Nemours & Co.; July 1, 1919.)

Ports for Tilting Furnace.—A. M. AUBERT of Billancourt, Seine, France, patents a new port for a tilting regenerative furnace, fired by liquid fuel, shown in Figs. 6 and 7. Each regenerator and the adjacent furnace and has a lunette (b) attached to it, but separated from each other by a space sufficient to allow entrance of a pipe carrying the liquid fuel. In the position shown, hot air from the regenerator (g)

largely are deflected inward and upward, blowing out the upper hole 4, there to be burned completely by auxiliary air drawn through the outer passages 9. The pot itself is protected from inward scour by a self-renewing layer of viscous fuel ash, while destruction by superheating is prevented by the air currents through 9. Clogging of the slag hole 6 is prevented by a portion of the flame pulsating downward at this point. (1,306,233-234-235; assigned to Schutz Hawley Co.; June 10, 1919.)

Molybdenum-Tungsten Alloy.—FREDERICK G. KEYES has patented a process for the manufacture of a molybdenum-tungsten alloy which

FIGS. 6 AND 7. A NEW PORT FOR A TILTING REGENERATIVE FURNACE

passes through the fire clay ports (d) into the furnace chamber (a), there burning the sprayed fuel. At the other end, the hot gases pass off through larger ports into another regenerator. Upon reversal, the fuel valves are changed, and all lunettes shifted as shown in dotted lines (Fig. 7), so that the small inlet ports may be replaced by larger exit ones and vice versa. (1,304,725; May 27, 1919.)

Burning Crushed Coal.—J. M. SCHULTZ of Chicago patents a method of burning crushed coal, and various forms of burners applicable. He proposes to take fuel and crush it as fine as practicable without previous drying, thus being much coarser than pulverized coal burned in suspension. This fuel is then blown into a burner at a uniform rate with sufficient air to burn the

dried, and then heated to 1200 deg. in a stream of hydrogen to reduce any molybdenum oxide that may have been formed during the drying and molding operations. The bar is again heated by an electric current until the temperature has attained that of the melting point of molybdenum. The alloy thus formed preferably contains about 20 per cent molybdenum, and when heated to between 800 and 900 deg. C. is both malleable and ductile. (1,308,907; assigned to Cooper-Hewitt Electric Co., July 8, 1919.)

Elimination of Carbon Dioxide and Oxygen From Electric Furnaces.—JOHN THOMSON of New York has patented a process by which the practical use of an electric resistor furnace, for the distillation of zinc, is made possible by covering the charge with a layer of granular carbon. The carbon resistor is located above the charge and heats by radiation through this granular layer, which is maintained at a temperature between 1000 and 1100 deg. C. At this temperature the following reaction takes place, from left to right:

Any oxygen present in the furnace will react with zinc to form "blue powder," and thus zinc oxide will be converted to metallic zinc and carbon monoxide according to the equation:

The granular carbon layer acts as a filter through which the zinc vapors and gases must pass, the oxygen and carbon dioxide being eliminated. (1,308,879, July 8, 1919.)

Sulphidizing Solution.—In view of the fact that the majority of plants using the sulphidizing process for the flotation of oxidized ores are so situated that the soluble sulphides required for the treatment have to be secured from distant points, RAYMOND F. BACON proposes to manufacture the desired sulphide solution at the flotation plant. Natural alkali and alkaline earth materials, such as lime and the carbonates, hydroxides and borates of the alkali or alkaline earth metals, are available in mining regions and afford a

FIG. 8. METHOD OF BURNING CRUSHED COAL

fixed carbon to CO through tangential tuyeres near the top of the annular pot shown in sectional perspective in Fig. 8. Here the contained water is first evaporated, then volatiles driven off, and the remaining coked particle pursues a downward helical path. By the time the coarsest piece is consumed, the remaining ash is fused, and this slag drips out of the lower hole 6 in liquid condition. The products of combustion

cheap source of alkali, while iron pyrites, copper pyrites, flotation concentrates, etc., may be used to supply the sulphur. A mixture of sulphur-bearing and alkali-bearing material in appropriate proportions is heated to 600-700 deg. C. in a retort or muffle, after a preliminary heating at a lower temperature to remove moisture and water of crystallization. The soluble sulphide formed during the heating may be extracted by leaching with water, or the contents of the retort may be introduced directly into the water of the sulphidizing tank and the sulphide solution formed *in situ*. (1,310,151; assigned to Metals Research Co. of New York; July 15, 1919.)

Continuous Distillation of Sludge Acid.—A furnace for the fractional distillation of sludge acid has been devised by INGENUIN HECHENBLEIKNER and PETER S. GILCHRIST of Charlotte, N. C. The furnace consists of an outer casing of acid-resisting masonry, provided with a grate and an ashpit. Through the top of this

FURNACE FOR CONTINUOUS DISTILLATION OF SLUDGE ACID

casing a cylinder of acid- and heat-resisting material projects into the body of the furnace, dividing the latter into two zones, each of which has a separate gas outlet. The top of this cylinder is closed with a bell hopper, through which coal may be fed as required, and is provided with a number of drip pipes for introducing the sludge acid. When coal is supplied to the furnace in sufficient quantity to maintain the upper level of the fuel bed within the cylinder, as shown in the illustration, a high-temperature zone is obtained in the lower fuel bed and a lower-temperature zone with the cylinder. The aqueous and tarry constituents of the sludge acid distill off during the passage of the acid through the low-temperature zone and pass to the tar condenser. The sulphuric acid vapors liberated in the high-temperature zone are collected in a separate condenser. Each condenser is provided with an exhaust fan for the removal of waste gases. (1,310,078; assigned to Chemical Construction Co.; July 15, 1919.)

Cellulose-Nitrate Composition.—A mixture which is capable of producing a very flexible, transparent and uniform film is obtained by incorporating in 65 parts of acetone or methyl alcohol 10 parts of cellulose nitrate and 2 parts of butyl oxalate. HANS T. CLARKE of Rochester, N. Y., states that the butyl oxalate may be replaced by any dialkyl ester of oxalic acid in which each of the alkyl groups contains 4 or 5 carbon atoms. The plasticity and flexibility of the composition may be increased by the addition of softeners, such as amyl acetate, ethyl propionate, urea, castor oil, triphenyl phosphate, dibutyl sulphone, etc. (1,309,981; assigned to Eastman Kodak Co., July 15, 1919.) Kodak Co., July 15, 1919.)

Personal

BRIG-GEN. AMOS A. FRIES has been awarded the Distinguished Service Medal for exceptionally meritorious and distinguished services, officially set forth as follows: "As chief of the Chemical Warfare Service, he was charged with the important task of training and equipping our troops for a form of warfare in which the American Army had had no experience prior to the present war. Both in securing proper defensive measures against gas and in developing new methods for its use as an offensive agency, he performed his arduous duties with marked success, thereby rendering valuable services to the American Expeditionary Forces."

MR. CHESTER H. JONES, formerly a Captain in the Chemical Warfare Service, has joined the editorial staff of **CHEMICAL & METALLURGICAL ENGINEERING**. His headquarters will be at the Chicago office of the McGraw-Hill Co. in the Old Colony Building.

PROFS. H. R. MOODY and **RESTON STEVENSON** will return to the College of the City of New York in September. Dr. Moody was special expert with the War Industries Board and Dr. Stevenson served in France as Major in the Sanitary Corps.

MR. ELLWOOD HENDRICK, consulting editor of **CHEMICAL & METALLURGICAL ENGINEERING**, has returned to New York after a month's trip to South America.

MAJOR MARION G. DONK of the Chemical Warfare Service, who was in charge of Government work on bromine production at the Dow Chemical Co. plant at Midland, Mich., has joined the staff of the Hercules Engineering Corporation.

LIEUT. CLIFFORD L. SNYDER, who has recently been discharged from the army, has joined the technical staff of the Detroit Testing Laboratory as sales engineer. Lieut. Snyder received his commission at Fort Sheridan, Illinois, and was later transferred to the Nitrate Division in charge of construction work at Plant No. 1, Sheffield, Ala.

Current Market Reports

The Non-Ferrous Metal Market

Monday, Aug. 11.—The non-ferrous metal market continues to be quiet, production is substantial and prices firm. Speculative buying is not so attractive as formerly.

Aluminum.—The market is quiet, 98-99 per cent ingots are now quoted at 33c. per lb. Scrap has declined; cast, 21-24c.; sheet, 22-25c.; and clippings 23-27c.

Antimony.—The market is easy, spot wholesale lots offering from 9-9-1/2c. and jobbing lots, 9-9-1/2c. per lb.

Copper.—Quotations have not changed. Spot 23-23-1/2c. September futures, 24c.

Copper sheets, hot-rolled.....	lb.	33.50	—
Copper sheets, cold rolled.....	lb.	35.00	—

The Iron and Steel Market

The monthly ingot report of the American Iron & Steel Institute shows that 2,508,176 gross tons of steel ingots were produced in July by 30 companies which in 1918 made 84.03 per cent of the industry's total ingot output. The indicated rate for the whole industry is 35,700,000 tons per annum, or 73 per cent of capacity, estimating capacity at 49,000,000 tons. Correspondingly June had shown 67 per cent, May 54 per cent and April 65 per cent. The figures indicate a dip to a rate of about 50 per cent at the middle of May, also to a rate of fully 75 per cent at the end of July, representing a gain of one-half in the rate in the short period of two and a half months. The year had opened up with production at about 87 per cent of capacity. Despite the wide fluctuation the rate in July and the average rate in the first half of the year were almost precisely the same, 72.3 per cent for the half-year and 72.9 per cent for July.

The Steel Corporation's unfilled obligations increased by 685,806 tons during July, this comparing with an increase of 610,545 tons in June, and decreases running quite uniformly, with an average of 640,000 tons a month, during the six months preceding, December to May inclusive. While the booking of actual shipping orders was heavy in June and July, particularly in July, the increase in the unfilled tonnage was of course due largely to the piling of contracts, as the monthly statement includes contract obligations. The total of such obligations at the end of July was 5,578,661 tons, equal to nearly six months of output, but the distribution as to products is such that in some lines a much longer period of time is represented and in other lines a much shorter period.

MARKET CONDITIONS IMPROVING

The steel market is no longer entirely one-sided. In April and the fore part of May there was nothing favorable. Orders were light, production was declining and prices were being shaded by many producers. In June there was improvement in all respects and in July the situation from all aspects was good, the various market indices being wholly favorable.

Now the condition and prospects of the market present two sides. There is room for discussion. Until recently the fact that an order was placed was proof positive that the material was needed, and immediately, for actual consumption. Since several branches of the finished steel trade have become sold up, immediate delivery of such products is not assured and is in fact practically impossible, and a portion of the buying now in progress may perhaps rest not upon absolutely known and immediate requirements but rather upon the desire of the jobber or manufacturing consumer to protect his future.

The general industrial developments of the first half of August have been quite unfavorable to the iron and steel industry. The greatest lack the steel market has had has been railroad orders, and the demands railroad labor has lately made prevent any hope of there being an early decision as to the future status of the railroads whereby steel orders involved in upkeep and betterments could be placed. The obviously growing labor unrest affects the steel trade at another point. Its lack, besides that of railroad buying, has been in orders involved in large construction or investment undertakings, along which line there has been relatively little steel demand. The new developments as to labor are such as to make the general investor more conservative, and the outlook for steel orders involved in investment projects is distinctly less favorable than 30 days ago, whereas a continued improvement had been expected.

Prospects have greatly diminished that there will be any important advances in the near future in either pig iron or steel prices. Until very recently there were many predictions that an advancing market was a matter of the very near future. It is doubtful whether the market was directly in line for advancing prices through the operation of the law of supply and demand, and it may be that the steel producers who predicted price advances did so from adherence to the steel trade's traditional philosophy that the way to stimulate buying is to have an advancing market. The Steel Corporation, however, had allowed it to become known quite plainly a couple of months ago that it was positively opposed to steel price advances, this year at least, and while the independents who favored advancing prices may have thought for a time that the Steel Corporation's hand could be forced, the universal outcry over the high cost of living and the general recognition of the interdependence of all commodity price advances with wage advances make price advances, no matter in what commodity, very unpopular.

SOME FURNACES ADVANCE PRICES ON PIG IRON

The pig iron market is not to be judged finally by surface indications. The Alabama furnaces have advanced to the \$26.75 price of March 21, placing them on a level, f.o.b. furnace, with many Northern furnaces when they have much freight to absorb to reach the limits of their usual distributing territory. Chicago district furnaces are reported to have advanced their prices \$2 a ton, and two Cleveland producers have announced advances of 50c. These incidents are not proof of fundamental strength in the pig iron market, which sometimes exhibits signs of advancing because conditions are unfavorable, and sometimes declines because prospects have improved. The reason for such divergences from what would be regarded as reasonable conduct for a commodity market is that a furnace must either run or not run, while a short blast is expensive. The furnaces in operation are well sold and if conditions are not sufficiently promising to induce idle furnaces to blow in, the furnaces that are sold up may very naturally advance their asking prices. Merchant pig iron was produced at 10 per cent lower rate in July than in June, which easily accounts for there being far from a plethora of pig iron, but the July output was not over about 55 per cent of capacity, and in such circumstances a general and genuine advance in prices actually paid for pig iron is quite improbable, and it would be at the same time entirely without precedent. When there are many idle furnaces a marked improvement in the outlook induces idle furnaces to decide to get into blast, and such decisions are always followed promptly by the selling of "backlog" tonnages, frequently at more or less concessions from the going market.

EXPORT TRADE

The smallest iron and steel exports since 1915 fell in February of this year, 234,793 gross tons. Thereafter there was continued improvement until 544,580 tons were reported for June. Export demand has been moderately uniform for several months and the June tonnage is probably fairly representative of what is to be expected for some time to come. To compare exports with productive capacity it is of course necessary to eliminate scrap, pig iron, castings, etc., and when this is done it is seen that the steel exports of June were at the rate of a trifle less than 6,000,000 tons a year, on the finished rolled steel basis, capacity in which may be taken at 37,000,000 gross tons a year. Thus, referring only to steel, June exports represented about 16 per cent of capacity, or about 24 per cent of production, since the mills were operating at about 67 per cent during the month.

The best export year before the war was 1912, with about 2,400,000 tons of rolled steel or equivalent exported, that being about 11 per cent of the year's production, or about 10 per cent of the existing capacity. Thus exports have increased by about 150 per cent. To use definite figures, capacity may be said to have increased by 13,000,000 tons a year and exports by 2,600,000 tons.

The Chemical Market

New York, August 9, 1919.

Trading in heavy chemicals continues brisk for both domestic and export account, with *sodium bichromate* still holding the center of interest. Practically no changes in price in the general list have developed. An abrupt slump in the hitherto active vegetable oils, a sharp rise on the part of spirits of turpentine, with other naval stores in sympathy, complete the salient features of the local market during the past two weeks.

HEAVY CHEMICALS

With only one manufacturer making *sodium bichromate*, this chemical has risen from 11-12c. per lb. to 15-16c., although car lots are offered at 14½c. The consuming demand is still large, most of the export shipments going to England. Heavy sales of *potassium carbonate* made to manufacturers in the Middle West and to Denmark are reported at 17c. per lb.

Caustic soda is holding firm at the quotation established three weeks ago, while export orders show a slight diminution.

Iodine, resublimed, having advanced abroad, local dealers are asking 25c. more than the previous quotation of \$4.25 per lb.

Better demand has led some manufacturers to advance *glycerine* 1c., making the present price 21c. per lb.

There has been a strike in the *phosphate* mining fields, particularly in Florida, for the past three months and this is still on. No phosphate has been shipped and it appears not likely that any will be for some time. *Phosphoric acid*, all *sodium phosphates*, *acid phosphates* and *fertilizers* are affected by the strike and are accordingly expected to rise.

COAL-TAR PRODUCTS

While there are no outstanding features among the coal-tar products, business in these items is on a firm footing with the increasing production of the textile mills gradually swelling the demand. Among the intermediates, aniline oil, aniline salts and dimethylaniline are being consumed in large volume. Following the advance in aniline oil recorded at the last writing, dimethylaniline has risen from the minimum quotation of 50c. to 52c. per lb. Quotations on *phenol* are nominal, pending the official announcement by the Government of the price at which its huge stock of this product is to be sold. Affected by this situation and the heavy demand, *salicylic acid*, U. S. P., is selling at 35-45c. per lb., the technical grade at 30-40c. per lb., in comparison with 30-35c. and 25-30c., respectively, two weeks ago.

VEGETABLE OILS

Vegetable oils are suffering a relapse from the active speculation of the past few months. The heavy buying from abroad has stopped abruptly as has the domestic. The present slump is attributable in the main to the instability of foreign exchange. The values of oils here have been augmenting while at the same time exchange has been declining. Buyers are between two fires and discreetly have withdrawn from the market. This condition is only temporary and within a short time satisfactory adjustments will be effected.

With the exception of cottonseed oil, there have been few changes in price on spot oil. Futures, however, dropped for a time, but are now back on the level and moving upward.

There have been serious losses of seed in some parts of the linseed-producing States. Until the new crop in November no improvement over present conditions is likely, especially as long as speculative interest is active. The trade is, therefore, awaiting developments while quotations remain unchanged.

NAVAL STORES

Two weeks ago spirits of turpentine was selling at \$1.25-\$1.27 per gal., which was a record figure. At this writing none is for sale in this market and it is nominally quoted at \$1.75-\$1.80. The market at Savannah is steadily advancing, having at present reached \$1.71½ per gal. Both export and domestic buying have vied in vigor, the former having

slightly the advantage. As a new feature, demand from Germany is reported increasing.

Likewise, stocks of rosins are exceedingly low with all grades bringing fancy prices.

Emulating the naval stores market, pine oil, steam distilled, has advanced 17c. per gal. from the previous quotation of 78c.

St. Louis, August 5, 1919.

HEAVY CHEMICALS:—The outstanding development in the local market in the past two weeks has been the heavy demand for 60 per cent sulphuric acid and the strong market for nitric acid. The latter was expected to show a sharp decline about Aug. 1, when Government support was removed, but it has more than held its own.

The heavy demand for 60 per cent sulphuric acid has forced the price up 50 cents a ton and it is now averaging \$12. The fertilizer people as usual are making the market and orders are coming in at such a rate that local producers are keeping busy.

The 66 per cent sulphuric acid is quiet at \$18 a ton. Business is good, especially if account is taken of slackness in steel-making, particularly marked at present in St. Louis, where many steel mills are running at low ebb.

Muriatic acid is quiet, 18 per cent selling for \$22 in tank car lots. *Sodium bisulphate (niter cake)* has changed little since the last report. Local producers report the demand steady and all their production taken.

Nitric acid was expected to slump badly, but has more than held its own since the last report, two weeks ago. The 40 deg. Baumé is selling at 10 and 10½ cents a lb., 38 deg. at 9 cents, and 42 deg. at 11 cents.

Zinc chloride is very active and an advance in price is looked for. The 50 per cent sells at 4 cents a lb. in tank car lots, and some sales have been reported as low as 3½ cents in spite of the advance of zinc.

Zinc oxide is reported strong by local producers. No price change has been made, but producers believe the persistent and heavy demand may force a rise. Prices remain at 8 to 9 cents a pound, according to lead sulphate content, in car lots and half a cent higher for smaller quantities.

Chicago, August 7, 1919.

In the main, the heavy chemical market is remaining firm, with almost the entire line in good demand, sodium bichromate still holding the local spot-light at a quotation of 15c. No fluctuation and no undue activity are apparent in the coal tar products, prices remaining the same. The pine tar line, however, is furnishing enough activity to make up for any lack of interest in other lines.

HEAVY CHEMICALS:—Sodium bichromate, on which a 4c advance was recorded on Aug. 1, is up 4½c more, to 15c a pound, with dealers having difficulty in supplying the demand. Potassium carbonate is being held at 19c with sales active. A quotation on yellow potassium prussiate of 68c is almost meaningless, as there is none to be had even at this figure. The red is also up 20c, \$1.10 being the current quotation, with supply very limited.

The acids show no change on the local market. Although sales of sulphuric have fallen off to some extent, \$18 a ton is still the quotation for 66-deg. With good demand, muriatic brings around \$22. Activity in sodium bisulphate (niter cake) is not so pronounced, and no change in price has been recorded. Bleach, caustic soda and soda ash are all quoted at prices ruling for the past thirty days.

VEGETABLE OILS:—This market shows the effect of recent speculation, in that a decided slump has occurred in several items. Linseed oil remains at \$2.48, with not much trading taking place. Soya bean oil and coconut oil are both off about two cents with holders of stock asking for bids. The quotation on bean oil to-day is 17c. Corn oil, and cottonseed oil both hold firm with fair demand.

FLATOTATION OILS, NAVAL STORES:—No one seems able to forecast the future for turpentine, \$1.65 being asked to-day and many sales being closed at that figure. The main question seems to be one of supplying the demand rather than one of price. It is freely predicted that without embargo turpentine will soon reach \$2. Rosin also is up, W.W. bringing \$25 and F \$21.50. Pine tar and pine tar oil show no change.

Nitric, 42 deg.....	lb.	07 - 07 1/2	08 - 08 1/2
Oxalic, crystals.....	lb.	24 - 25	25 - 30
Phosphoric, Ortho, 50 per cent, solution	lb.	09 - 10	10 - 14
Picric.....	lb.	30 - 40	50 - 14
Pyrogallol, resublimed.....	lb.		2.30
Sulphuric, 60 deg., tank cars.....	ton	12.00 - 14.00	
Sulphuric, 60 deg., drums.....	ton	17.00 - 20.00	22.00 - 25.00
Sulphuric, 60 deg., carboys.....	ton	16.00 - 18.00	23.00 - 26.00
Sulphuric, 60 deg., tank cars.....	ton	20.00 - 21.00	25.00 - 26.00
Sulphuric, 60 deg., drums.....	ton	25.00 - 26.00	30.00 - 40.00
Sulphuric, fuming, 20 per cent, (oleum) tank cars.....	ton	22.00 - 27.00	
Sulphuric, fuming, 20 per cent, (oleum) drums.....	ton	25.00 - 32.00	
Sulphuric, fuming, 20 per cent, (oleum) carboys.....	ton	30.00 - 35.00	
Tannic, U. S. P.....	lb.		1.30 - 1.40
Tannic (tech.).....	lb.		42 - 46
Tartaric, crystals.....	lb.		1.20 - 1.40
Tungstic, per lb. of WO.....	gal.	4.00 - 1.20	4.85 - 1.23
Alcohol, Ethyl.....	gal.	0.31 - 0.44	0.44 - 0.44
Alcohol, Methyl.....	gal.	0.08 - 0.09	0.08 - 0.09
Alum, potash lump.....	lb.	15 - 16	18 - 20
Alum, chrome lump.....	lb.	01 - 02	02 - 02 1/2
Aluminum sulphate, commercial.....	lb.	02 - 03	03 - 03 1/2
Aluminum sulphate, precip.....	lb.	07 - 09	09 - 10
Aqua ammonia, 26 deg., drums (750 lb.)	lb.		30 - 35
Ammonia, anhydrous, cylinders (100-150 lb.)	lb.	13 - 14	14 - 14 1/2
Ammonium carbonate, powder.....	lb.	12 - 13	13 - 14
Ammonium chloride, granular (white salamoniac).....	lb.	12 - 13	13 - 14
Ammonium chloride, granular (gray salamoniac).....	lb.	12 - 13	13 - 14
Ammonium nitrate.....	lb.	05 - 06	06 - 07
Ammonium sulphate.....	lb.	05 - 06	06 - 07
Amyl acetate.....	gal.		3.65 - 0.94
Arsenic, oxide, lump.....	lb.		09 - 09 1/2
Arsenic sulphide, powdered.....	lb.		28 - 33
Barium chloride.....	ton	75.00 - 80.00	85.00 - 100.00
Barium dioxide (peroxide).....	lb.	22 - 24	24 - 26
Barium nitrate.....	lb.	10 - 10 1/2	11 - 12
Barium sulphate (precip.) (blanc fixe).....	lb.	02 - 03	03 - 04
Bleaching powder (see calcium hypochlorite).....	lb.		02 - 04
Blue Vitriol (see copper sulphate).....	lb.		65 - 75
Borax (see sodium borate).....	lb.		2.00 - 2.05
Bromine.....	lb.		65 - 75
Calcium acetate.....	cwt.	2.00 - 2.05	2.10 - 0.05
Calcium carbide.....	lb.		19.00 - 25.00
Calcium chloride, fused, lump.....	lb.	01 - 01 1/2	02 - 02 1/2
Calcium chloride, anhydrous.....	lb.	01 - 01 1/2	02 - 02 1/2
Calcium hypochlorite (bleaching powder).....	cwt.	1.75 - 1.80	2.00 - 2.50
Calcium peroxide.....	lb.		1.50 - 1.70
Calcium phosphate, monobasic.....	lb.		25 - 25 1/2
Calcium sulphate, precipitated.....	lb.		09 - 09 1/2
Carbon bisulphide.....	lb.	05 - 06	06 - 07
Carbon tetrachloride, drums.....	lb.	11 - 12	12 - 14
Carbonyl chloride (phosgene).....	lb.		75 - 100
Caustic potash (see potassium hydroxide).....	lb.		09 - 09 1/2
Caustic soda (see sodium hydroxide).....	lb.		09 - 09 1/2
Chlorine, gas, liquid-cylinders (100 lb.).....	lb.	05 - 06	06 - 08
Cobalt oxide.....	cwt.	1.00 - 1.20	1.50 - 1.65
Copper (see iron sulphate).....	lb.		1.00 - 1.10
Copper carbonate, green precipitate.....	lb.		28 - 31
Copper cyanide.....	lb.		65 - 70
Copper sulphate, crystals.....	lb.	08 - 09	09 - 09 1/2
Creosol (see tartar emetic).....	lb.		09 - 09 1/2
Epsom salt (see magnesium sulphate).....	lb.		20 - 21
Formaldehyde, 40 per cent.....	lb.		20 - 21
Glauber's salt (see sodium sulphate).....	lb.		20 - 21
Iron oxide, red.....	lb.		4.50 - 0.06
Iron sulphate, (copperas).....	cwt.	1.00 - 1.20	1.50 - 1.65
Lead acetate, non-aqueous.....	lb.		15 - 17
Lead arsenate (paste).....	lb.		85 - 86 1/2
Lead nitrate, crystals.....	lb.		09 - 10
Litharge.....	lb.		13 - 14
Lithium Carbonate.....	lb.		13 - 14
Magnesium carbonate, technical.....	lb.		13 - 14
Magnesium sulphate, U. S. P.....	100 lb.	2.00 - 2.63	2.75 - 3.00
Magnesium sulphate.....	100 lb.	1.75 - 2.00	2.00 - 2.25
Nickel salt, double.....	lb.		14 - 15
Nickel salt, single.....	lb.		15 - 16
Phosgene (see carbonyl chloride).....	lb.		70 - 100
Phosphorus, red.....	lb.		65 - 70
Phosphorus, yellow.....	lb.		35 - 37
Potassium bichromate.....	lb.	25 - 28	35 - 40
Potassium bitartrate (cream of Tartar).....	lb.		55 - 60
Potassium bromide, granular.....	lb.		49 - 50
Potassium carbonate, red.....	lb.	60 - 65	70 - 75
Potassium carbonate, crude.....	lb.	12 - 13	20 - 25
Potassium chlorate, crystals.....	lb.	24 - 25	30 - 35
Potassium cyanide, 98-99 per cent.....	lb.		35 - 40
Potassium hydroxide (caustic potash).....	lb.		32 - 35
Potassium iodide.....	lb.		3.55 - 3.60
Potassium nitrate.....	lb.	19 - 21	21 - 25
Potassium permanganate.....	lb.		55 - 60
Potassium prussiate, red.....	lb.		90 - 100
Potassium prussiate, yellow.....	lb.		90 - 100
Potassium sulphate.....	ton	225.00 - 230.00	

		Carlots	Less Carlots
Rochelle salts (see sodium potas., tartrate).....	ton	12.00 - 18.00	
Sal ammoniac (see ammonium chloride).....	ton		1.19 - 6.61
Salt cake (see sodium carbonate).....	ton		1.19 - 6.61
Silver cyanide.....	lb.		671 - 681
Silver nitrate.....	lb.		1.85 - 1.90
Soda ash, light.....	100 lb.	1.85 - 1.90	2.00 - 2.10
Soda ash, dense.....	100 lb.	2.25 - 2.30	2.40 - 2.50
Sodium arsenate.....	lb.	06 - 07	07 - 08
Sodium bicarbonate.....	100 lb.	2.35 - 2.40	2.75 - 3.00
Sodium bichromate.....	lb.	14 - 15	15 - 16
Sodium bisulphate (nitre cake).....	ton	3.00 - 8.00	10.00 - 11.00
Sodium sulphate.....	ton	1.80 - 1.90	2.00 - 2.10
Sodium borate (borax).....	lb.	07 - 08	08 - 09
Sodium carbonate (soda ash).....	100 lb.	1.35 - 1.50	1.50 - 1.75
Sodium chlorate.....	lb.	15 - 16	16 - 18
Sodium cyanide.....	lb.	30 - 31	31 - 34
Sodium fluoride.....	lb.	13 - 14	14 - 15
Sodium hydroxide (caustic soda).....	100 lb.	2.75 - 2.90	3.50 - 3.75
Sodium molybdate.....	lb.	2.50 - 3.25	3.25 - 4.00
Sodium nitrate.....	100 lb.	3.00 - 3.25	3.75 - 4.00
Sodium nitrite.....	lb.	09 - 10	10 - 11
Sodium peroxide, powdered.....	lb.		30 - 32
Sodium phosphate, dibasic.....	lb.	03 - 04	04 - 05
Sodium potassium tartrate (Rochelle salts).....	lb.		18 - 19
Sodium prussiate, yellow.....	lb.	01 - 02	02 - 02 1/2
Sodium silicate, solution (40 deg.).....	lb.	02 - 02 1/2	02 - 02 1/2
Sodium silicate, solution (60 deg.).....	lb.	02 - 02 1/2	02 - 02 1/2
Sodium sulphate, crystals (Glauber's salt) cwt.....	cwt.	1.05 - 1.35	1.50 - 2.00
Sodium sulphide, crystal, 60-62 per cent (conc).....	lb.		05 - 06
Sodium sulphite, crystals.....	lb.	03 - 04	04 - 05
Strontium nitrate, crystals.....	lb.		03 - 04
Sulphur, flowers.....	lb.		31 - 36
Sulphur, roll (brimstone).....	ton	35.00 - 37.50	
Sulphur dioxide, liquid, cylinders.....	100 lb.	3.05 - 3.65	3.60 - 4.00
Sulphur (sublimed), flowers.....	100 lb.	2.70 - 2.90	2.90 - 3.50
Sulphur, roll (brimstone).....	ton	35.00 - 37.50	
Tin bichloride (stannous).....	lb.		48 - 49
Tin oxide.....	lb.		60 - 61
Zinc carbonate, precipitate.....	lb.		12 - 13
Zinc chloride, gran.....	lb.	12 - 13	13 - 14
Zinc cyanide.....	lb.	49 - 50	50 - 51
Zinc dust.....	lb.	09 - 11	11 - 14
Zinc oxide, dry American.....	lb.		10 - 13
Zinc sulphate.....	lb.	03 - 04	04 - 04 1/2

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities.

		Carlots	Less Carlots
Alpha naphthol, crude.....	lb.	\$1.00 - \$1.10	
Alpha naphthol, refined.....	lb.	1.40 - 1.50	
Alpha naphthylamine.....	lb.	.35 - .50	
Aniline oil, drums extra.....	lb.	.25 - .30	
Aniline salts.....	lb.	.28 - .33	
Anthracene, 80% in drums (100 lb.).....	lb.	.90 - 1.00	
Benzaldehyde (l.f.c.).....	lb.	1.00 - 1.15	
Benzenidine, base.....	lb.	.95 - 1.15	
Benzenidine, sulphate, sublimed.....	lb.	.95 - 1.15	
Benzoic acid, U. S. P.....	lb.	1.00 - 1.10	
Benzoate of soda, U. S. P.....	lb.	.95 - 1.10	
Benzol, pure, water-white, in drums (100 lb.).....	gal.	.24 - .28	
Benzol, 90% in drums (100 lb.).....	gal.	.23 - .27	
Benzyl chloride, 95-97%, refined.....	lb.	.35 - .40	
Benzyl chloride, tech.....	lb.	.25 - .35	
Beta naphthol benzoate.....	lb.	3.75 - 4.50	
Beta naphthol, base.....	lb.	.45 - .55	
Beta naphthol, tech.....	lb.	.45 - .55	
Beta naphthylamine, sublimed.....	lb.	2.25 - 2.35	
Creosol, U. S. P., in drums (100 lb.).....	lb.	.18 - .25	
Ortho-creosol, in drums (100 lb.).....	lb.	.23 - .27	
Creosylic acid, 92-98%, straw color, in drums.....	gal.	.85 - .90	
Creosylic acid, 95-97%, dark, in drums.....	gal.	.80 - .85	
Creosylic acid, 50% first quality, drums.....	gal.	.60 - .65	
Dichlorobenzol.....	lb.	1.50 - 2.25	
Diethylaniline.....	lb.	.52 - .57	
Dimethylaniline.....	lb.	.25 - .37	
Dinitrobenzol.....	lb.	.25 - .37	
Dinitrochlorobenzol.....	lb.	.45 - .55	
Dinitronaphthalene.....	lb.	.45 - .55	
Dinitrophenol.....	lb.	.30 - .32	
Dinitrofluorobenzol.....	lb.	.38 - .45	
Dipic acid, 25% tar acids, car lots, in drums.....	gal.	.70 - .75	
Diphenylamine.....	lb.	1.75 - 2.25	
H-acid.....	lb.	1.20 - 1.80	
Metaphenylenediamine.....	lb.	1.20 - 1.80	
Monochlorobenzol.....	lb.	.10 - .14	
Monochloroethane.....	lb.	1.00 - 1.25	
Naphthalene crushed, in bbls. (250 lb.).....	lb.	.06 - .08	
Naphthalene, flakes.....	lb.	.06 - .07 1/2	
Naphthalene, base.....	lb.	.08 - .10	
Naphthalene, crude.....	lb.	.10 - .12	
Nitrobenzol.....	lb.	.13 - .15	
Nitronaphthalene.....	lb.	.35 - .45	
Nitro-toluid.....	lb.	1.30 - 1.75	
Ortho-amidophenol.....	lb.	4.25 - 5.00	
Ortho-dichlorobenzol.....	lb.	.15 - .20	
Ortho-nitrophenol.....	lb.	.90 - 1.00	
Ortho-nitro-toluid.....	lb.	.25 - .30	
Ortho-toluidine.....	lb.	.45 - .50	
Para-amidophenol, base.....	lb.	2.60 - 3.50	
Para-amidophenol, HCl.....	lb.	2.75 - 3.25	
Para-dichlorobenzol.....	lb.	.10 - .12	
Paranitraniline.....	lb.	1.00 - 1.25	
Para-nitro-toluid.....	lb.	1.35 - 1.50	
Paraphenylenediamine.....	lb.	2.75 - 4.00	
Para-toluidine.....	lb.	1.30 - 1.75	
Phthalic anhydride.....	lb.	.75 - 2.15	
Phenol, U. S. P., drums (deat.), (240 lb.).....	lb.	.10 - .13	
Pyridin.....	gal.	2.50 - 3.75	
Resorcin, technical.....	lb.	3.50 - 7.25	
Resorcin, pure.....	lb.	6.50 - 7.25	
Salicylic acid, tech., in bbls. (110 lb.).....	lb.	.30 - .40	
Salicylic acid, U. S. P.....	lb.	.35 - .45	
Salol.....	lb.	.80 - 2.15	
Solvent naphtha, water white, in drums, 100 gal. gal.....	gal.	.22 - .27	
Solvent naphtha, crude, 100 gal. gal.....	gal.	.19 - .24	
Sulphanilic acid, crude.....	lb.	.25 - .30	

Tolidine.....	lb.	1.75	2.50
Tolidine, mixed.....	lb.	.45	.80
Toluid, in tank cars.....	gal.	.22	.24
Toluid, in drums.....	lb.	.23	.30
Nyldine, drums, 100 gal.....	lb.	.44	.46
Nylo, pure, in drums.....	gal.	.37	.45
Nylo, pure, in tank cars.....	gal.	.33	.35
Nylo, commercial, in drums, 100 gal.....	lb.	.23	.27
Nylo, commercial, in tank cars.....	gal.	.22	

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow.....	lb.	\$0.44	\$0.45
Beeswax, refined, yellow.....	lb.	.48	.49
Beeswax, white pure.....	lb.	.65	.68
Carnauba, No. 1.....	lb.	.88	.90
Carnauba, No. 2, regular.....	lb.	.65	.68
Carnauba, No. 3, Regular Country.....	lb.	.58	.60
Japan.....	lb.	.18	.21
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb.	.06	.06
Paraffine waxes, crude, nodule 124-126 m.p.....	lb.	.06	.06
Paraffine waxes, refined, 118-120 m.p.....	lb.	.07	.08
Paraffine waxes, refined, 128-130 m.p.....	lb.	.08	.09
Paraffine waxes, refined, 130-135 m.p.....	lb.	.10	.11
Paraffine waxes, refined, 135-137 m.p.....	lb.	.12	.13
Stearic acid, single pressed.....	lb.	.25	.27
Stearic acid, double pressed.....	lb.	.28	.29
Stearic acid, triple pressed.....	lb.	.30	.33

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal.	\$0.95	
Pine oil, pure, dest. dist.....	gal.	.85	
Pine tar oil, ref., sp. gr. 1.025-1.035.....	gal.	.45	
Pine tar oil, ref., sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.....	gal.	.33	
Pine tar oil, double ref., sp. gr. 0.965-0.990.....	gal.	.65	
Pine tar, ref., thin, sp. gr. 1.080-1.960.....	gal.	.34	
Turpentine, crude, sp. gr. 0.900-0.970.....	gal.	.85	
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....	gal.	.27	
Pine wood creosote, ref.....	gal.	.48	

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.....	280 lb.	\$18.00	
Rosin E-I.....	280 lb.	18.50	20.50
Rosin K-N.....	280 lb.	24.50	25.50
Rosin W, G-W.....	280 lb.	23.50	25.50
Wood rosin, bbl.....	280 lb.	17.70	18.00
Spirits of turpentine.....	gal.	1.75	1.80
Good turpentine, steam dist.....	gal.	1.65	1.70
Wood turpentine, dest. dist.....	gal.	1.55	
Pine tar pitch, bbl.....	200 lb.	8.25	8.50
Tar, kiln burned, bbl (500 lb.).....	bbl.	12.75	13.50
Retort tar, bbl.....	280 lb.	13.75	14.50
Rosin oil, first run.....	gal.	.86	.91
Rosin oil, second run.....	gal.	.88	.93
Rosin oil, third run.....	gal.	.90	1.07
Rosin oil, fourth run.....	gal.	.93	1.10

Solvents

70-72 deg., steel bbls. (85 lb.).....	gal.	\$0.33	
70-72 deg., steel bbls. (85 lb.).....	gal.	.31	
68-70 deg., steel bbls. (75 lb.).....	gal.	.30	
V. M. and P. naphtha, steel bbls. (85 lb.).....	gal.	.23	

Crude Rubber

Para-Upriver fine.....	lb.	\$0.54	\$0.54
Upriver coarse.....	lb.	.31	.31
Upriver cauchó ball.....	lb.	.31	.31
Plantation—First latex crepe.....	lb.	.41	.41
Ribbed smoked sheets.....	lb.	.41	.41
Brown crepe, thin, clean.....	lb.	.24	.24
Amber crepe No. 1.....	lb.	.36	.37

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls.....	lb.	\$0.19	\$0.20
Castor oil, AA, in bbls.....	lb.	.21	.22
China wood oil, in bbls.....	lb.	.22	.24
Cocoonut oil, Ceylon grade, in bbls.....	lb.	.19	.20
Cocoonut oil, Java grade, in bbls.....	lb.	.21	.22
Corn oil, crude, in bbls.....	lb.	.24	.25
Cottonseed oil, crude (f.o.b. mill).....	lb.	.21	.25
Cottonseed oil, summer yellow.....	lb.	.28	.29
Cottonseed oil, winter yellow.....	lb.	.28	.30
Lined oil, raw, car lots.....	gal.	2.20	2.22
Lined oil, raw, tank cars.....	gal.	2.17	2.20
Lined oil, boiled, car lots.....	gal.	2.24	2.25
Olive oil, commercial.....	lb.	2.30	2.50
Palm, Lagos.....	lb.	.17	.18
Palm, bright red.....	lb.	.16	.17
Palm, Niger.....	lb.	.16	.17
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.27	
Peanut oil, refined, in bbls.....	lb.	.29	.30
Rapeseed oil, refined in bbls.....	gal.	1.55	1.60
Rapeseed oil, black, in bbls.....	gal.	1.60	1.70
Soya bean oil, tank cars (Manchurian), in bbls.....	lb.	.19	.20
Soya bean oil, black cars, f.o.b., Pacific coast.....	lb.	.16	.17

FISH

Winter pressed Menhaden.....	gal.	\$1.28	\$1.35
Yellow bleached Menhaden.....	gal.	1.37	
White bleached Menhaden.....	gal.	1.32	1.38
Blown Menhaden.....	gal.	1.38	1.40

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, flatted.....	ton	\$25.00	\$36.00
Barytes, off color.....	ton	20.00	25.00
Blanc fixe, dry.....	lb.	.031	.043
Blanc fixe, pulp.....	ton	35.00	47.50
Caslin.....	lb.	.18	
Chalk, English, extra light.....	lb.	.05	.07
Chalk, English, light.....	lb.	.04	.06

Chalk, English, dense.....	lb.	.04	.05
China clay (Kaolin), imported, lump.....	ton	25.00	35.00
China clay (Kaolin), imported, powdered.....	ton	30.00	60.00
China clay (Kaolin), domestic, lump.....	ton	10.00	20.00
China clay (Kaolin), domestic, powdered.....	ton	25.00	40.00
Feldspar.....	ton	11.50	15.50
Fluorspar, acid grade, lump, f.o.b. mines.....	net ton	\$30.00	\$35.00
Fluorspar, acid grade, crushed, f.o.b. mines.....	net ton	35.00	45.00
Fuller's earth, domestic, powdered.....	ton	30.00	40.00
Fuller's earth, imported, powdered.....	ton		
Pumice stone, imported.....	lb.	.03	.06
Pumice stone, domestic.....	lb.	.02	
Shellac, TN.....	lb.	1.10	
Shellac, D. C.....	lb.		
Shellac, V. S.....	lb.		
Shellac, Diamond I.....	lb.		
Shellac, orange, fine.....	lb.		
Shellac, orange, superfine.....	lb.	.25	
Shellac, A. C. garnet.....	lb.		
Shellac, bleached, bone.....	lb.	1.40	
Shellac, bleached, fresh ground.....	lb.	1.10	
Soapstone.....	ton	15.00	25.00
Talc, domestic.....	ton	16.00	20.00
Talc, imported.....	ton	35.00	60.00

Refractories

Following prices are f.o.b. works:

Chrome brick.....	net ton	90-100 at Chester, Penn.
Chrome cement.....	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay.....	net ton	35-45 at Clearfield, Penn.
Clay brick, 2nd quality.....	net ton	30-35 at Clearfield, Penn.
Magnesite, dead burned.....	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4 1/2 x 2 1/2.....	net ton	40-50 at Chester, Penn.
Silica brick.....	net ton	41-45 at Mt. Union, Penn.

Ferro-alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$250.00	
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon.....	lb.	.30	.40

White lead, dry and in oil, 25 and 50 lb. cans.....	lb.	.13	
White lead, dry and in oil, 5 lb. cans.....	lb.	.15	

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.....	100 lb.	\$2.45	
Angles, 3 to 6-in, 1-in. thick.....	100 lb.	2.45	
Tees, 3-in. and larger.....	100 lb.	2.45	
Plates.....	100 lb.	2.66	
Rivets, structural, 1-in. and larger.....	100 lb.	4.20	
Sheets, conehead for boilers, 1-in. and larger.....	100 lb.	4.30	
Sheets, No. 28 black.....	100 lb.	4.35	
Sheets, No. 10 blue annealed.....	100 lb.	3.55	
Sheets, No. 28 galvanized.....	100 lb.	5.70	

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c. all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

JOHNSON—The Mines & Development Co. has taken over the Arizona-Michigan property here and plans to improve same and also build a 50-ton concentrator.

California

REDLANDS—The University of Redlands has awarded the contract for the construction of a 2-story, 60 x 120-ft. Science Hall, including laboratories, etc., to W. C. Crowell, 440 Chaniber of Commerce Bldg., Pasadena.

Connecticut

HARTFORD—The Hartford Rubber Works, Bartholomew Ave., plans to erect a 6-story, 100 x 300-ft. addition to its factory. Lockwood, Greene & Co., 60 Federal St., Boston, Mass., engineer.

MANCHESTER—The Oxford Soap Co. Hilliard St., plans to build a factory addition, including a grinding mill. Estimated cost, \$40,000.

STAMFORD—The city plans to build a sewage disposal plant. Estimated cost, \$25,000.

STRATFORD—The city has awarded the contract for the construction of a sewage disposal plant, chlorine-treatment house, tidal basin, sludge bed, etc., to the Eastern Engineering & Construction Co., 55 Main St., Bridgeport. Estimated cost, \$175,000.

Kansas

GALENA—The Silver Fox Lead & Zinc Co. plans to build a new mill to replace the one destroyed by fire on June 29 and is in the market for entire concentrating plant equipment. F. Childress, general manager.

Maryland

TOWSON—The Commissioners of Baltimore County will receive bids until Aug. 18 for the construction of a sewage disposal plant, Imhoff tanks, dosing chamber, trickling filters, etc. Estimated cost, \$100,000. Norton, Bird & Whitman, 606 Munsey Bldg., Baltimore, engineers.

Massachusetts

PROVINCETOWN—The East Harbor Fertilizer Co., 293 Bridge St., Springfield, plans to construct a 2-story, 70 x 75-ft. fertilizer plant. Estimated cost, \$30,000. C. N. Flagg Co., Springfield, engineer.

WILLIMANSETT (Holyoke P. O.)—The Paper Makers Chemical Co., 629 Main St., has awarded the contract for the construction of a 1-story factory, to P. J. Kennedy & Co., Inc., 464 Maple St., Holyoke. Estimated cost, \$75,000.

Michigan

DETROIT—The city plans to construct the Connors Creek sewage system on Connors Rd.; treatment works to comprise a battery of 40 Imhoff tanks. Estimated cost, \$14,000. C. W. Hubbell, City Hall, engineer.

DETROIT—The Fisher Body Corp., Piquette Ave., has awarded the contract for the construction of a 6-story, 156 x 551-ft. paint shop on Piquette Ave. and St. Antoine St. to H. C. Christman Co., 315 Stevens Bldg. Estimated cost, \$1,200,000. Noted Aug. 1.

Minnesota

ADRIAN—The city is having surveys made by Druser & Smith, engineers, Globe Bldg., St. Paul, for the construction of a new sewerage system and a disposal tank. Estimated cost, \$40,000. M. E. Corrigan, village clerk.

ATKIN—Hallam, city commissioner, is receiving bids for installing one purifier, one water filter, one 150-hp. Corliss type steam engine, one electric generator, 125 kw. current, one coal conveyor and 50,000-gal. steel or wood water tank.

ROCHESTER—F. A. Bricker and G. J. Patterson, Fargo, N. D., and A. C. Fawcett, Rochester, plan to build a 6-story, 46 x 142-ft. dental clinic. Estimated cost, \$300,000.

Missouri

CAMELION—The city will soon award the contract for the construction of a filtration plant. Estimated cost, \$35,000. E. E. Harper, 2408 East 30th St., Kansas City, engineer. Noted May 15.

DUENWEG—The M. & T. Mining Co. plans to move its mill from Granby District and erect same here, and is in the market for boiler, steam engine and compressor rolls. R. McGee, general manager.

MILAN—The city will soon award the contract for the construction of complete sanitary sewers and a disposal plant. Estimated cost, \$40,000. Archer & Stevens, New England Bldg., Kansas City, engineers.

ST. LOUIS—The American Syrup Preserving Co., East Union Ave. and Terminal R. R., has awarded the contract for the construction of a 3-story, 55 x 70-ft. factory at 5125 Penrose Park, to B. J. Charville, 310 Chestnut St. Estimated cost, \$50,000.

Montana

HELENA—The State Board of Health plans to build a laboratory. Estimated cost, \$55,000.

SCOBEY—The City Council will soon award the contract for the construction of sanitary sewers, manholes, settling tank and sludge beds. Estimated cost, \$45,000. W. B. Sanders, Helena, engineer.

Nebraska

HARVARD—The city plans to construct sanitary sewers and a sewage disposal plant. Estimated cost, \$50,000. Grant, Fulton & Letton, 505 Bankers' Life Bldg., Lincoln, engineers.

New Jersey

NEWARK—The Max Hertz Leather Co. is having plans prepared for the construction of a 3-story, 42 x 200-ft. factory addition on Oliver St. Estimated cost, \$150,000. James A. Pigott, 9 Clinton St., engineer.

NEWARK—The Radell Leather Co. has had plans prepared for the construction of a 1-story, 50 x 60-ft. factory addition on Wilson Ave. Estimated cost, \$10,000. J. A. Pigott, 9 Clinton St., engineer.

PLEASANTVILLE—The city has awarded the contract for the construction of a sanitary sewerage system, to Edwin G. Britz, 1769 Park Ave., New York City. Estimated cost, \$86,310.

TRENTON—The Albano Manufacturing Co., manufacturer of shoe past, 701 Case St., has awarded the contract for the construction of a 1-story, 50 x 90-ft. factory, on Oakland Ave., to Samuel Tietz, 469 Brunswick Ave. Estimated cost, \$14,890. Noted July 1.

TRENTON—The Trenton Electric & Conduit Co., 3 Tyler St., plans to construct a 2-story plant for the manufacture of porcelain. Estimated cost, \$10,000.

WESTMONT—The city has awarded the contract for the construction of a 9-mile sanitary sewerage system, etc., to W. Penn Corson, 1141 Sycamore St., Camden, at \$68,416. Noted July 1.

New York

KINGS PARK—The State Hospital Commission, Capitol, Albany, received bids for the construction of a sewage disposal plant, at Kings Park State Hospital, from General Co., Inc., 603 5th Ave., \$3,320. New York Sewerage Disposal Co., 37 East 24th St., \$8,650. Slattery Engineering & Construction Co., Inc., 7 East 42nd St., \$10,787. Estimated cost, \$17,707. Noted Aug. 1.

SYRACUSE—The Board of Education of Onondaga plans to erect a 2-story, 150 x 200-ft. school. A chemical laboratory will be installed in same. Estimated cost, \$18,000. Ford, Busk & Sheldon are Prospect St., Hartford, Conn., engineers.

SYRACUSE—The N. L. Underberg Brass Co., 804 East Water St., will receive bids until Aug. 25 for the construction of a 1-story brass foundry on Water St. Estimated cost, \$40,000. Melvin I. Kling, Snow Bldg., engineer.

WEST ENDICOTT (Endicott P. O.)—The Endicott Johnson Co., Johnson City, plans to erect a 3-story concrete tannery and a 2-story shoe factory at West Endicott. Estimated cost, \$350,000.

Ohio

ALLIANCE—The city will hold an election Sept. 8, to vote on \$25,000 bonds for the erection of a gas plant.

CLEVELAND—The Atlantic Foundry Co., 7510 Morgan Rd., has awarded the contract for the construction of a 1-story, 26 x 36-ft. addition to the Cleveland Pratt Co., 801 Columbia Bldg. Estimated cost, \$5,000. Noted Aug. 1.

CLEVELAND—The Cleveland Fruit Juice Co., 1390 West 9th St., plans to build a 3-story, 100 x 140-ft. factory on Euclid Ave. and London Rd. Estimated cost, \$30,000.

CLEVELAND—The Cuyahoga Galvanizing Co., 1280 East 59th St., plans to construct a 1-story, 60 x 160-ft. factory at 3352 Payne Ave. Estimated cost, \$10,000.

CLEVELAND—The Glidden Varnish Co., Madison Ave. and Berea Rd., is having plans prepared for the construction of a 4-story 63 x 90-ft. grinding building on Madison Ave. Estimated cost, \$60,000. Osborn Engineering Co., 2843 Prospect Ave., engineer.

CLEVELAND—The Orth Brass & Aluminum Castings Co., 1378 East 33rd St., plans to build a 2-story, 32 x 78-ft. factory. Estimated cost, \$10,000.

TOLEDO—The City Council is having plans prepared for the installation of twenty-two new filters of 1,000,000-gal. daily capacity, a 150 x 500-ft. settling basin of 1,250,000-gal. capacity and several miles of 30, 32 and 40 in. C. I. mains. Bonds for \$50,000 have been voted for project. H. C. McClure, 229 Valentine Bldg., engineer.

Oklahoma

DOUTHAT—The Dudley Milling Co. plans to erect a tailing mill to treat tailings from Admiralty No. 2 and is in the market for a gas engine rolls, 14-iron, elevator pulleys and belts. C. Theurer, mpt.

EL RENO—The City Clerk will soon receive bids for enlarging the sewerage system and Imhoff sewage disposal plant. Estimated cost, \$95,000. H. G. Powell, Box 20, engineer.

HARTHORNE—The city plans an election Sept. 2 to vote on bonds for the construction of a water purification plant. V. V. Long & Co., Oklahoma City, consulting engineer.

HOCKEYVILLE—The Hope Lead & Zinc Co. plans to move the old Cornett Mill from Quapaw and erect same here, and is in the market for gas engines, compressor and tables. W. Henton, supt.

PICHER—W. & H. Loran & Co., Hockerville, plans to move the old Cornett Mill from north of Blue Mound to Picher, and is in the market for tables, rolls, shafting, pulleys and belting. F. Slick, general manager.

ST. LOUIS—The Underwriters Land Co., Picher, plans to erect a complete new concentrating plant at their No. 4 shaft, and is in the market for entire equipment for same. F. N. Bendelari, general manager.

STROUD—The city is having plans prepared by Johnson & Bernhardt, engineers, Pleasant Bldg., Kansas City, Mo., for laying 24,000 ft. of sewers and installing Imhoff tank. Estimated cost, \$75,000.

Oregon

BEND—The Oregon Nitrate Co. plans to develop Stinking Lake and Shew Mountains nitrate deposits by installing crystallization evaporating system and crushing plant. Estimated cost, \$25,000. J. H. Morgan, Bend, president.

Pennsylvania

FARMERVILLE—Morris Knowles, engineer, Jones-Law Bldg., Pittsburgh, has awarded the contract for the construction of a sewage disposal plant for the Cona-

ers Mining Co., to Pihl & Miller, Wabash Bldg. Estimated cost, \$10,000. Inbott tanks will be installed in same.

PHILADELPHIA—The Philadelphia Paper Manufacturing Co., 231 South Front St., has awarded the contract for the construction of a 1-story, 55 x 192-ft. factory on Nixon and Pottsville Sts. to the Brown Construction Co., 4600 Main St. Estimated cost, \$25,000.

PHILADELPHIA—Powers, Weightman & Rosenkranz Co., 916 Parrish St., has awarded the contract for the construction of a 5-story chemical factory, to R. C. Ballinger & Co., 218 North 13th St. Estimated cost, \$45,000.

PITTSBURGH—The United Engineering & Foundry Co. is having preliminary plans made for the construction of a 2-story, 45 x 100-ft. foundry and office buildings on 54th St. Hunting-Dans Co., Century Bldg., architect.

SCRANTON—The Heath Silk Co. plans to construct a 3-story, 50 x 100-ft. silk mill on Wyoming Ave. Estimated cost, \$66,000. G. N. Edson, Connell Bldg., architect.

Rhode Island

FAWTCUCKET—The Halliwell Co., Blackstone Ave., has awarded the contract for the construction of a 2-story, 60 x 105-ft. addition to its bleachery, to the Cruise & Seely Construction Co., 188 Main St. Estimated cost, \$40,000.

PROVIDENCE—The U. S. Gutta Percha Co., 12 Dudley St., has awarded the contract for the construction of a 5-story, 60 x 100-ft. steel addition to its plant, to Williams & Merchant, Inc., 86 Weybosset St. Estimated cost, \$30,000.

EL PASO—The city plans an election to vote on \$100,000 bonds for the construction of a septic tank.

STRAWN—The Palo Pinto Oil Co., 61 Broadway, New York City, has awarded the contract for the construction of a gasoline extraction plant to Westinghouse, Church, Kerr & Co., 87 Wall St., New York City. Estimated cost, \$50,000.

Utah

SALT LAKE CITY—Headlund & Kent, engineers, Dooley Bldg., will soon award the contract for the construction of a 10-ton oil distilling plant for the Rainbow Petroleum Oil Products Co. Estimated cost, \$25,000.

Washington

SPOKANE—The Shell Oil Co., of California, North 111 Green St., plans to enlarge its plant here. Estimated cost, \$100,000.

SPOKANE—The Spokane Drug Co., 707 Railroad Ave., plans to build a 5-story, 116 x 142-ft. drug factory on Wall St. and Railroad Ave. Estimated cost, \$200,000.

West Virginia

PARKERSBURG—The city has awarded the contract for the construction of a crib filter at the filtration plant, to the Western Rivers Co., Point Pleasant, estimated cost, \$20,545. The city will furnish necessary cast iron pipe.

Ontario

BRANTFORD—The Brantford Smelting Co. has awarded the contract for the construction of a 100 x 200-ft. tin smelting plant, to F. H. Secord, 133 Nelson Ave. Estimated cost, \$50,000.

KINGSTON—The Department of Public Works, Ottawa, has awarded the contract for the construction of a sewage system and disposal works at the Sydenham Military Hospital, to W. H. Harvey, Kingston. Estimated cost, \$10,403.

KITCHENER—The Canadian Consolidated Rubber Co., 137 King St., plans to construct a 4-story rubber factory at 413 Strange St. Estimated cost, \$1,000,000.

LONDON—C. S. Hyman Co., Ltd., Richmond St., will soon award the contract for the construction of a 5-story, 150 x 300-ft. cannery on St. George St. Estimated cost, \$300,000. H. C. McBride, Molsons Bank, architect. Noted July 15.

LONDON—The McClary Manufacturing Co., 333 Wellington St., manufacturer of enamelware, tinware, etc., plans to build a 5-story, 72 x 120-ft. addition to its factory. Estimated cost, \$60,000. J. M. Moore, 425 Richmond St., architect.

SAULT STE. MARIE—The Airona Steel Co. plans to build a 1-story structural steel plant. Estimated cost, \$300,000.

WINDSOR—The city has had plans prepared by F. W. Thorold, engineer, 166 Avenue Rd., Toronto, for the construction of a pumping station and filtration plant for the border cities of Windsor, Sandwich, Walkerville, etc. Estimated cost, \$100,000.

Cuba

HAVANA—The Air Reduction Co., 120 Broadway, New York City, has awarded the contract for the construction of a 2-story, 98 x 103-ft. acetylene plant, to Hamilton & Chambers, 29 Broadway, New York City. Estimated cost, \$100,000.

Coming Meetings and Events

THE AMERICAN CERAMIC SOCIETY will hold a meeting in Chicago, Sept. 24.

THE AMERICAN CHEMICAL SOCIETY will hold its Fall meeting in Philadelphia, Pa., Sept. 2-6 inclusive.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its Fall meeting in Chicago, Sept. 23-25 inclusive.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its 1919 convention in Philadelphia, Sept. 29 to Oct. 4.

THE AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition of gas appliances and apparatus, at the Hotel Pennsylvania, New York, Oct. 13 to 18.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its Fall meeting in Chicago, Ill., Sept. 22-27.

THE AMERICAN STEEL TREATERS' SOCIETY will hold its first annual convention in Chicago, Ill., Sept. 22-27.

THE FIFTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in Chicago, Ill., Sept. 22-27 inclusive.

THE INSTITUTE OF METALS Division of the I. M. E. will hold its next meeting in Philadelphia, Pa., Sept. 29 to Oct. 4.

THE INSTITUTE OF METALS will hold its Autumn meeting in Sheffield, England, Sept. 24-25.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its Fall meeting in Chicago from Sept. 24 to 27.

Industrial Notes

THE MCGRAW-HILL BOOK Co. celebrated its 10th anniversary on July 1, 1919, and issued a booklet entitled "10 Years." For over 20 years prior to July 1, 1909, the Book Department of the McGraw Publishing Co. and the Hill Publishing Co. has been producing books in very special fields. The consolidation has resulted in "better books in text and manufacture," as well as in greatly increased prestige and service. From 200 titles 10 years ago, the list has grown to approximately 1000. Sales during the war were unusually large owing to the demand for highly specialized engineering books. Under special contracts with the Navy Department the Company produced 20 new texts for the aviation and submarine sections. For the Khaki University 1500 packing cases containing 150,000 books were shipped overseas.

THE SOCIÉTÉ DE VALEURS FOUR PERS ET ACIER (Society for Values of Iron and Steel) in Schaffhausen, Switzerland, reports Consul General L. J. Keena at Zurich has established in Zurich a metallurgical exchange, the purpose of which is to bring together every Friday buyers and sellers of machines of every description and of all kinds of metals used in the manufacture of machinery. The exchange solicits the membership of foreign engineers and exporters of raw materials and calls particular notice to the advantages which a foreign member will have in the marketing of his products in Switzerland, and to the attention of manufacturers desiring to import. The fee for such membership is \$5 a year.

ARTHUR D. LITTLE, INC., Cambridge, Mass., announces the resignation of vice-president Mr. Harry S. Mork, who has been elected to the vice-presidency of the Lustron Co. of Boston. This concerns manufacturers artificial silk by a process developed in the Little Laboratories.

THE PORTABLE MACHINERY Co., Passaic, N. J., has issued a circular entitled "Welcome Fair Competition." It briefly describes one concern has kept and is trying to market an imitation of the Scoop

conveyor. A suit is pending for infringement of rights and purchasers are warned against the imitation.

THE ELECTRIC FURNACE CONSTRUCTION Co., Finance Bldg., Philadelphia, Pa., has received orders for Greaves-Etchells electric furnaces for the railroad machinery Co. and the Imperial Japanese Mint; the latter is for the manufacture of coinage bronze.

THE CUTLER-HAMMER Mfg. Co., Milwaukee, Wis., has opened offices at 905 Kresge Bldg., Detroit, Michigan. Mr. H. S. Kinsey is in charge and has taken with him from the Chicago office Messrs. C. W. Greenman and M. Dugless, both of whom were recently mustered out of the service.

THE CHICAGO PNEUMATIC TOOL Co., Chicago, Ill., announces the appointment of Mr. N. S. Thulin as special railroad representative on the staff of Mr. S. C. Sprague, manager of Western railroad sales. It is also announced that the Minneapolis office of this company will move to Fifth Avenue and Fifth Street South.

Fifth National Exposition Of Chemical Industries

IN THE last week in September chemistry moves to Chicago, along with the National Exposition of Chemical Industries. This will be the fifth of the kind and it bids fair to outstep all previous efforts.

The value of these expositions has been proved many times, and many things have been learned both by the management and by exhibitors. For instance, it is not profitable to draw a crowd just to show something unusual. The rubberneck is not a purchasing organism. On the other hand, whenever a betterment or economy is made clear and evident to the understanding mind, it brings immediate response and inquiry. In other words, the Exhibition is one of applied technology, and not a demonstration in popular science. As an inducement to fond mothers to bring along their little Reginalds and Harolds, with a view to persuading them to study science and become great chemists, the show does not even attempt to function. To the chemical engineer it grows more interesting every year. To the—we may almost say millions of collectors of advertising catalogues who seem to visit every exposition to improve their minds by walking over miles of floor space, we are glad to say it bids less and less encouragement as the years roll on.

Jointly with the first Exposition was held the annual meeting of the American Electrochemical Society, and it was a great success. The following year the American Chemical Society as well as its Electrochemical cousin had an annual meeting during the Exposition. This proved too much of a good thing, for it was beyond physical endurance to be present at the many sessions that almost commanded attendance. The following year there were no meetings except the important symposia which constitute a daily feature. This year, with the exception of the American Chemical Society, the time is to be embellished with annual meetings of five important organizations: The American Electrochemical Society, the Technical Association of Pulp and Paper Manufacturers, the American Steel Treating Society, the American Mining and Metallurgical Engineers and the American Ceramic Society, which will all meet in conjunction with the show. And there are to be symposia and discussions and, as likely as not, manifestoes and declarations.

The program which we give in a special insert for the convenience of our readers is very elaborate and replete with interest. It should not be forgotten that the Exposition is going on at full tilt during all these frequent intellectual and occasional gustatory festivities. The list includes the various general and sectional meetings of the societies named with the exception of

those of the American Ceramic Society, which are not fully determined upon the time of our going to press. In addition to these and the meetings arranged for by the management of the Exposition, there will occur on Friday, the 26th inst., an event of historic interest; consisting in the award of the Willard Gibbs medal by the Chicago Section of the American Chemical Society to Professor W. A. NOYES.

The whole occasion is planned on a large scale, and we are heartened by the fact that, as our people begin to see the incidence of chemistry upon industry on every hand, they are getting the opportunity to learn how it touches them.

The management spends some 51 diligent weeks every year in getting the Exposition together and arranging the details. The result is a very concentrated show which technical chemists can ill afford to miss.

Shabby Treatment of Patent Examiners

THE Commissioner of Patents testified before the House Committee on Patents last month that resignations from his staff had increased from about 8 per cent in 1915-16 to over 25 per cent per annum in 1918-19. And under date of Aug. 26 the Civil Service Commission announces examinations to be held for "Patent Investigator (Male) \$1200 to \$1800 a year." For those having had the necessary preliminary instruction and three years' experience the opportunity is also offered to advance to "Expert Patent Investigators at \$1800 to \$2400 a year."

This reminds us of a picture lately printed, of a man applying for a position. The prospective employer declares that they require two years' post-graduate work and five years' professional practice and that the salary is \$1800 a year. The applicant says, "Say, Boss, I ain't never had no education," to which the employer replies, "Oh, excuse me! Welcome to our works. Your wages will be \$7 a day. Come with me."

The service affords excellent training for men who want to become patent solicitors and attorneys, but we are not short of patent attorneys. There are enough of them to take care of the business offered. On the other hand there is a serious shortage of good examiners. The salaries paid do not make the posts attractive except to those who intend to enter legal practice, and these may be expected to leave as soon as they feel themselves capable. From an economical standpoint a young man stands as good if not a better chance if he goes "braking" on a railroad. Of course he would miss the pleasant living conditions and de-

lightful society that Washington offers when the stress of war is raised, but this applies particularly to applicants of a gregarious nature. Many are not. And if the applicant regards the salary of \$100 a month as good pay—it being nearly the price of unskilled labor with steady work—it may be that he lacks the natural gifts to be a good patent investigator.

Once upon a time there were two children of poor but honest parents. "I will be a barber when I grow up," said the boy. "It is light, easy work and there are tips for nearly every job." "And I," said his sister, "will be a manicure and then I may marry a prominent club man or a millionaire." But they bethought themselves that public school teachers have three months vacation every summer, and so they became teachers. Thus were an excellent barber and a natural born manicure lost to society, while the educational system of their native city was not at all improved by their presence as instructors.

This fable teaches us that in the Patent Office the requirements for mental equipment are different from those of a barber shop. Comment on desirable compensation is superfluous.

Does American Potash Need a Fixed Price?

AMERICAN potash appears at once to be the child and victim of propaganda. First we had no industry because the Germans assured us that their proven resources of crude salt which could be cheaply mined and shipped in quantity gave them domination over the world. Then when the blockade prevented importation of this desirable substance, the price soared to dizzy heights, and Americans were spurred by an insistent cry, "Give us potash!" to get into the game patriotically and make some money. Apparently there was money to be had, for newspapers far and wide, including those no less respectable and reliable than the *Chicago Tribune*, published "stories" a column long about the fabulous fortunes suddenly acquired by Nebraska potash magnates. No one seemed to take the trouble to deny these wild tales, perhaps because they attracted needed capital to the infant industry and increased our potential supply of salts, or because one recognizes that reasoning beings do not believe such lurid stories should they by chance be read. Here was a grievous sin of omission, however, for the selfsame "potash magnates" are now hard put to explain why they still need the fostering care of governmental price fixing and the limitation of imports to allow them to live and, as they put it, to "reorganize on a peace basis."

There is no question that the production of American potash in quantity is essential for our national well-being. No American wants us again to be dependent solely upon the Germans for any substance required in our domestic economy. If he knows the true story, he will not begrudge the fancy price he had to pay for war-time production. But isn't it about time, after five years of absolute embargo and high returns, that the infant industry show signs of being able to stand on its own feet? If it cannot approach that point under such conditions will it ever be able to walk alone? Will costs in this and other instances have to be indefinitely upheld by the power of a government whose people are demanding relief from high prices with a voice never before so unanimous or insistent?

The truth of the matter is this: That the American potash industry can stand on its own feet, and can now compete with foreign importations, barring dumping, trade war, rebates and such unfair practices; and the sooner the American potash industry comes before the people of the United States with clean hands the better it will be for its good name. Of course there is more money to be had, and that easily, by getting a price fixed for its production, at say \$2.50 per unit, than there is in devising ways and means to cut its own costs so they are proof against competition. It's good business, too, the kind of good business that has placed the world over a trembling volcano of industrial unrest. But the other is the good technology which CHEMICAL & METALLURGICAL ENGINEERING will always insist upon: The production of more material for a smaller expenditure of labor and money, an increase in the efficiency of effort and dollars, and the only apparent escape from the present *cul-de-sac* of high wages but higher prices.

Mr. W. E. RICHARDSON, of the Nebraska Potash Producers' Association, and Mr. A. C. HARRAGIN, secretary of the American Trona Corporation, have presented detailed costs of producing potash in 1918 before the House Committee on Ways and Means in support of the so-called licensing bill, which may be restated as follows:

	Nebraska		Trona	
	Per Ton of Crude Salt 20% K ₂ O	Per Unit K ₂ O (20 Lb.)	Per Ton of Chloride 50% K ₂ O	Per Unit K ₂ O (20 Lb.)
Fuel, labor, repairs, selling and overhead.....	\$37.80	\$1.89	\$32.97	\$0.66
Freight on salt to market.....	13.00	.65	17.72	.35
Capital charges.....	16.40	.82	61.71	1.24
Royalty.....	17.60	.88		
Total.....	\$84.80	\$4.24	\$112.40	\$2.25

The less said about the unholy figure for royalty the better. Capital charges appear to be high, especially for the Trona company, where, strangely enough, it is nearly twice as much as the entire operating expense. The bulk of these charges appears to be amortization of investment, designed to be entirely liquidated in two years—evidently unreasonable for going concerns, such as we hope to prove the potash industry to be. Freight is something outside the power of the producer, unless he ships a more concentrated salt. That brings us back to the net operating—\$1.89 a unit (9½ c. a lb.) in Nebraska and \$0.66 a unit (3.3 c. a lb.) at Searles Lake.

Nebraska operators evaporate brackish lake water to dryness, and it costs them 9½ c. to put each pound of potash in the resulting crude on cars at no profit! The water is there for the pumping. No purification of any sort is necessary. Merely evaporate 60 lb. of water and sack the dirty crystals. Just how careful of outgo the Nebraska men must have been may be judged by a comparison with the beet sugar industry. These men can pay 4 c. per lb. to the farmers for the sugar in the beets, collect them by rail, wash, shred and leach the cosettes, evaporate the solution, crystallize and purify the sugar, add in all capital charges and sell refined sugar at wholesale at 9 c. a lb. and still get rich at it! Or compare the cost of the Trona company—3.3 c. per lb. At Searles Lake the brine is not only evaporated, originally more concentrated, it is true, but in addition a quite delicate separation of large percentage of deleterious salts is necessary before the crystals can be sold.

Using multiple-effect crystallizing evaporators and filters, with reasonably good boiler practice, Nebraska

potash can unquestionably be produced f.o.b. factory now at \$0.66 per unit, the same as the Trona product, including all charges except capital charges—interest and depreciation. Accepting Mr. SHARP's statement that four plants with actual output in 1918 of 12,750 tons pure potash cost \$2,500,000, capital charges of 34c. per unit would equal 17 per cent for interest and depreciation. Mr. HAREAGIN, by the way, asks for only an ultimate 23c. Consequently with correct technology, the average plant operating on brines—and this source yielded three-quarters of our last year's supply—will not go into bankruptcy if it can get \$1 a unit for its potash, f.o.b. plant. Even though the pre-war cost of German potash, f.o.b. American ports, was \$0.75 a unit, it is not likely that this price can be approached for some time—in fact future delivery of Alsatian salts has been quoted at \$1.70 per unit, even though spot American potash is being sold at \$2.25.

Everything considered, it appears certain that the American industry need not fear strangulation from fair foreign competition. In fact, we believe that eventually potash from cement kilns, iron furnaces and sugar mills will command the market and give the brine plants cause for most worry. Who will protect them against this competition, if they do not immediately clean house and reduce their costs, which they admit they can do? In our opinion the potash industry would have the best chance of success if it went before the Tariff Commission, Congress and the President and said: "We can put potash aboard cars as cheaply as the European can put it aboard ships. All we ask is that their advantage in ocean freight rate over our long rail-haul be equalized by a proper protective tariff." This would square them with the only rational tariff policy acceptable to both political parties, disarm suspicion of ulterior motives, eliminate obnoxious licensing and price fixing, and unite all candid members of the industry solidly behind the movement.

A Truce in Labor Demands

THERE is no doubt that President WILSON's statement made public August 26 will mark the turning point in labor demands. The occasion of the President's utterance was his giving advice that the demands upon the Railroad Administration by the railroad shopmen should not be granted, but he was clear and emphatic in indicating that his observations were of general application. He spoke of "the demands of the shopmen and all other demands." He said, "It is the duty of every citizen of the country to insist upon such a truce" and he appealed to his "fellow citizens of every employment to co-operate in insisting upon the maintaining of such a truce."

The basic idea is that which has been in the minds of most employers and thinking men, that these continued wage advances get us nowhere. The increase in production cost is added, with an increment, to the producer's selling price, and more is tacked on along the line. Then the wage earner experiences more "high cost of living" and makes a fresh demand. The thing to do is to reduce the cost of living and "any substantial increase of wages in leading lines of industry at this time would utterly crush the general campaign the Government is waging, with energy, vigor and substantial hope of success, to reduce the high cost of living."

There can be no doubt that when the President mentioned "leading lines of industry" he had in mind the

case of the iron and steel industry. Six days before the President issued his statement the American Federation of Labor's "National Committee for Organizing Iron and Steel Workers" had announced the result of its "strike vote," taken during the 30 days preceding, as 98 per cent affirmative and had appointed a committee of six to seek a conference with the iron and steel producers, the committee having until August 30 to arrange for a conference, failing in which it was authorized to call a strike.

The American Federation of Labor demands were embodied in a platform of twelve planks, given to the press July 20 after the meeting of representatives of 24 unions who decided to take a "strike vote." The strategy was good. The unions represented included those of machinists, bricklayers, molders, plumbers and steam fitters, switchmen, stationary firemen, electrical workers and similar crafts. Many of these unions have strong memberships employed outside the iron and steel industry and the withdrawal of a few of the crafts would greatly cripple mill and furnace operations, even though the strikers comprised but a very small percentage of the total number of men employed. The strategy lay in attempting to produce a strike with a small number of men, the strike being to force complete unionization of the industry. The organizing committee would furnish simply the skeleton and the employers themselves would be required to fill out and make the organization complete.

This was aimed at by nothing less than the odious "check-off" which was No. 9 of the twelve demands, No. 1 being "collective bargaining." These two points, however, would merely establish the union. To make a union function as union men want unions to function the man must be made a non-entity, with no personality, no particular degree of skill, nothing to distinguish him from other men. To destroy individuality, to kill efficiency and to complete the surrender of the plants to the men, the following requirements were incorporated in the demands: No. 7, "Standard scales of wages for all crafts and classifications of workers," and No. 10, "Principle of seniority to apply in maintaining, reducing and increasing working forces." Lest it be thought that these two demands would represent so utter a surrender that nothing further could be asked, it must be mentioned that there were two more along this line, No. 2 calling for "Reinstatement of all men discharged for union activities with pay for time lost," when of course the claim would be made that all union men discharged had been discharged on that account, and No. 12, "Abolition of physical examination of applicants for employment." That is a confession that the organizers consider it profitable under the liability laws for a workman to be injured, even though it was not the injured who was physically unfit, but his fellow workman.

It is significant that in the platform as a whole demands representing directly or indirectly wage advances or decreases in the hours of labor were distinctly subsidiary, though of course such demands would be insisted upon. Granting the demands would involve not only the increase in production cost directly arising from higher wage rates and shorter hours but also a great increase due to lessened efficiency, and it is well indeed that the American Federation of Labor program has been dealt a stunning blow by the pronouncement of the President that there must be a truce in these things.

Western Chemical and Metallurgical Field

Colorado Potash Company

THE following brief description of the Colorado Potash Co.'s activities has been given to us by Dr. J. Gillingham Hibbs of Denver, Colo. The company was organized and operated by Fuller-MacCulloch Co., a partnership consisting of Messrs. Edmund Fuller and Thomas MacCulloch, both of Denver, who have been developing a process for the production of potash by the electrolytic decomposition of feldspar and leucite under a patent recently issued.¹

Feldspar is found within 20 miles of Denver in ample quantity for any production hoped for in that region, and is mined by benching in the open. This matter of proximity of supply yields a low cost of raw stock. The rock is crushed to about 60 mesh, decomposed in digesting pans and electrolyzed in special earthenware cells to potassium aluminate, with an accompanying complete segregation of the silicon content of the rock.

The crux of the process is the diaphragm cell. This special porous pot contains the cathode, immersed originally in pure water contained within the diaphragm. Surrounding this and inclosed in the cell body itself is the sulphuric acid solution of decomposed feldspar, in which the anode is immersed. Impressed current now ionizes the solution, and the alkali and aluminum travel through the diaphragm, forming KAlO_2 at the cathode, while amorphous silicon remains as a sludge about the anode. By insertion of proper tanks and pumps the electrolysis can be made continuous, fresh solution replacing the silica-bearing sludge, and water the alkaline aluminate.

The KAlO_2 is broken down by action of CO_2 , resulting in aluminum hydrate and K_2CO_3 ; the latter remaining in solution while the $\text{Al}(\text{OH})_3$ is precipitated. The K_2CO_3 solution is decanted, the remaining aluminum hydrate washed and dried by an atomizing process. The potash solution is now in a condition for the production of any desired commercial salt. This liquor contains practically 100 per cent potassium or sodium carbonates, the potash content being in the same ratio as in the original feldspar. With the material used the potassium salts will be greater than 90 or the sodium salt less than 10 per cent. There is no magnesium in it, wherein it differs from the Nebraska and Salt Lake brines. It is also free from chlorides, which is a feature of leading importance in tobacco fertilization.

At present the firm is addressing itself to the production of 100 per cent soluble K_2SO_4 , which is accomplished by digestion with gypsum, whereby a pure calcium carbonate is precipitated. The solution is decanted, or after washing the precipitate the solution is also dried by an atomizing process.

Work is now under way to perfect various mechanical features of the process, particularly washing and handling the flocculent alumina precipitate. This, being free from iron and other deleterious impurities, should be available for the production of metallic aluminum. Large quantities of amorphous silica, containing some aluminum compounds, are also separated from the circulating electrolyte, and this mate-

rial will probably be welcomed by the ceramic industry. When the problems in chemical engineering connected with the production of potash salts have been solved in the present small-scale unit, the company intends to install duplicate cells and equipment in its roomy plant sufficient to produce 300 tons K_2SO_4 per month, with its accompanying 165 tons Al_2O_3 and 700 tons silica. Eventually, the company plans erecting numerous plants near agricultural centers, where sufficient supplies of potash-feldspars, gypsum and phosphate may be obtained, and market a 100 per cent soluble material comprising a balanced proportion of potash, phosphate and nitrate.

Preliminary experimentation has convinced Dr. Hibbs and his associates that they can eventually supply the Middle West with its fertilizer requirements in potash and potash in combination with nitrogen and phosphorus at less than pre-war costs, provided, always, the farmer can be educated to the use of concentrated plant foods. A model garden of 14 acres is in preparation to demonstrate the advantages in the use of pure salts over fertilizers having a large filler content.

The Vanadium Situation

The demand for alloy steels containing vanadium is large and there will undoubtedly be an increasing demand for these alloys. The automotive industry is active, particularly in the production of trucks and tractors, and this industry is the largest consumer of these steels at present. However, the stock on hand seems to be sufficient for requirements and the market is quiet. Ferrovandium, 30 to 40 per cent, is quoted at \$5.50 to \$7 per pound of contained vanadium.

About three-fifths of the vanadium consumed in this country is obtained from Peru. The remainder is produced from deposits in the Western States and of this about nine-tenths is mined at Vanadium, Colo. Scattered mines, principally in Arizona and New Mexico, supply the remainder, excepting a small amount which is produced as a by-product from radium ores. The American Vanadium Co. produces ferrovanadium from the South American ores and the Primos Chemical Co. from domestic ores, these two companies being the largest in the field. The mill of the Primos Chemical Co., which was destroyed by fire, has been rebuilt and started operating at full capacity Aug. 1.

The trend of ferrovanadium prices will probably be determined by the cost of production from the domestic ores. It is also probable that this trend will be upward due to high wages, increasing depth of mining operations and a decreasing quality of ores obtained. This upward tendency should be checked by the production from as yet undeveloped sources and by the substitution of other alloy steels, particularly molybdenum.

Cuprodesclowitz and vanadinite are possible sources of supply. Metallurgical methods for the treatment of these ores have been published.* A zinco-desclowitz has been discovered in Nevada; the quantity of this mineral available has not been determined as yet nor has a method been worked out for its metallurgical treatment. A large deposit, for a vanadium ore, occurs in the Shattuck-Arizona mine at Bisbee.

*"Treatment of Cuprodesclowitz for the Extraction and Recovery of Vanadium, Lead and Copper"; J. E. Conley, CHEM. & MET. ENG., vol. 20, p. 465.

"A Proposed Metallurgical Process for the Treatment of Vanadinite for the Recovery of Lead and Vanadium"; J. E. Conley CHEM. & MET. ENG., vol. 20, p. 514.

¹Potash Extraction, 1,253,560, Jan. 15, 1919.

Utah Copper Tailings Pond

With the growth of mining acreage and the scale of milling operations, the Utah Copper Co. encountered the problem of properly disposing of the tremendous amounts of tailings produced daily at its two mills. Thus, the early estimates of ore reserves at the mine in Bingham Canyon were 37,500,000 tons and, in 1907, the mill was expected to handle perhaps 5000 tons of ore daily. By purchase of the Boston Consolidated and other properties in the canyon, the existing ore reserves have now been increased ten

ponds with dikes paralleling the two transcontinental railroads on the north and south, with a maximum height of 92 ft., at an estimated cost of \$3,885,000. Such a mass of loose material in close proximity to the railroads would be a continual menace to their operation, and these schemes were abandoned.

It then appeared necessary to move the railroads. If they were shifted about a half-mile north and connected with the old lines at the old Garfield station, a dike about 30 ft. high would be needed to impound all tailings resting at a grade of 0.9 per cent. The cost of this scheme was about \$2,265,000. However, by moving the tracks still farther north, and rebuilding the Garfield station, a tailings area of 6000 acres could be provided, sufficient for all material, at an average slope of about 0.92 per cent without its toe encroaching on the railroads; in other words, without the necessity of diking, except, perhaps, to impound and clarify water before drainage into the lake. This plan, which was adopted, cost about \$910,000, chiefly for new lands and railroad revision. The latter item was by agreement done without cost to the railroads, a new roadbed being provided equal to the old, \$2000 per mile allowed for extra surfacing work until the roadbed settled, and an amount capitalized at \$46,000 for additional expense of operation due to added distance and curvature.

The North Tailings Pond, which was originally from 6 to 12 in.

under water, was first drained by digging the ditches eventually needed for tailings water, and the embankments made by drag-line excavator at a cost of 25c. per yard.

The 12-ft. dike is 7 miles long, furnished to a top width of 10 ft. for a railway track to handle rippaging, which latter is smelter slag placed for about 80c. per cubic yard.

Statistics on Turpentine and Rosin

As an aid to the development of the naval stores industry, statistics regarding production and supply of turpentine and rosin are being collected by the United States Department of Agriculture through specialists in the Bureau of Chemistry.

Blanks on which to report have been sent to all producers and users in the United States whose names and addresses are available. This information will show the amount on hand April 1, 1919, the quantity made this season up to Aug. 1, the amount actually on hand at the stills Aug. 1, and the estimated production for the balance of the season. It is expected that the data will be published by Sept. 1.

Similar statistics regarding last season's production and available supply of rosin and turpentine proved to be of much interest to producers and consumers alike. Information regarding last season's output, or blanks for reporting this season's supply, may be obtained upon application to the United States Department of Agriculture, Washington, D. C.

times, to 374,000,000 tons, despite mining in the meantime more ore than twice the original estimate. Milling during 1918 proceeded at the rate 33,317 tons daily, and the rated capacity of concentrators and leaching plant is no less than 43,000 tons. As Mr. H. C. Goodridge, their chief engineer, pointed out at a recent meeting of the Utah Society of Engineers, a tenfold increase in available ore and a ninefold increase in milling capacity has rendered insufficient the originally ample tailings area.

A map shown herewith gives a general idea of the location of the mills and smelter near the Great Salt Lake shore. The southwestern portion of this mapped area is rough, the Bingham & Garfield and Denver & Rio Grande railways skirting the Oquirrh Mountains, which rise directly out of the flatlands surrounding Salt Lake. Thus the mills are constructed on a hillside about 125 ft. above the general ground level to the north. Across this marshy flat some mile and a half away were situated the main lines of two transcontinental railways, and the intervening area has been used for tailings since the commencement of operations.

Various schemes for enlargement were studied by the mining company's engineers. Should all the expected ore be impounded in the so-called West and East Tailings ponds, it would require dikes around the area to an average height of 80 ft. and an eventual slope on top of the pond of but 0.5 per cent. The total estimated cost of this scheme was \$1,680,000. Another plan was based on making two independent

War-Time Activities of Dye Plants in Germany

THE report of the British mission appointed to visit enemy chemical factories in the occupied zone was introduced at the dyestuffs hearings before the House Committee on Ways and Means, in order to emphasize the military value of a well-developed chemical industry. The following data have been taken from this report. In some cases difficulty was experienced in obtaining accurate details of manufacture, especially as regards substances which have a peace value, and the information must be accepted with some reserve on this account, although it was checked by cross-examination of the officials concerned and by a careful examination of the plant admittedly employed for war purposes.

Some years before the war a combination was formed by the Bayer, Badisché and A. G. F. A. companies and somewhat later a second group was formed which included Meister, Lucius & Bruning, Casella & Kalle. During the war these two groups amalgamated, and the Griesheim Elektron, Weiler-ter-Meer, Leonhardt and other smaller companies entered the combination, which is known as the I. G. (Interessengemeinschaft). It was largely owing to the efforts of this combination that Germany was enabled to continue the war in spite of the blockade. The I. G. works produced the bulk of the synthetic ammonia and nitric acid needed for the production of fertilizers and explosives, all the poison gas (with the exception of some chlorine and phosgene), and a large proportion of the high explosives.

The following are the more important works of the I. G. which were not visited, as they are outside the occupied zone:

Factories of the Aktien Gesellschaft für Anilinfabrikation.

Factories of the Griesheim Elektron Gesellschaft.

Factory of the Bayer Co. at Elberfeld.

Factory of the Badische Co. at Merseburg.

Factory of Casella & Co., Mainkur, near Frankfurt.

Factory of Leonhardt & Co., Mulheim, near Frankfurt.

A summary of the information obtained as to the war production of the factories visited is given under the headings of "Initial Products," "Explosives and Poison Gases."

INITIAL PRODUCTS FOR MANUFACTURE OF EXPLOSIVES AND POISON GAS.

The principal materials concerned are ammonia, nitric acid, sulphuric acid and chlorine, and it was on the output of these that the war production of chemical munitions depended. The expansion of output by the factories of the I. G. combination during the war is shown by Tables I-IV.

Explosives. No arrangements appear to have been made prior to the outbreak of war to utilize the resources of any of the dye factories for war purposes, and on mobilization their chemists were called up for military service. After the battle of the Marne the government realized the need for expanding the output of explosives and most of the chemical works were producing small quantities by the end of 1914. The demands made on them increased during 1915, but it was not until 1916 that plant was laid down to assist in the enormous production of explosives required by the Hindenburg program. Most of the big extensions of the synthetic ammonia and of the nitric and sulphuric acid plants date from this time, many chemists

being released from the army and the scientific staff of some of the works being augmented. Standardized plant used for the manufacture of dyes was converted for the production of explosives with remarkable speed;

TABLE I.—AMMONIA (METRIC TONS NH₃ PER DAY)

	1914	1918
Oppau.....	25	250
Merseburg.....	Nil	400
Total.....	25	650

TABLE II.—NITRIC ACID (METRIC TONS 100 PER CENT ACID PER DAY)

	1914	1918
Leverkusen.....	56	180
Hochst.....	150	375
Oppau.....	7	100
Ludwigshafen.....	(7) 40	40
Weiler-ter-Meer.....	12	24
Total.....	258	719

* Oppau has the power to produce now 500 tons HNO₃ daily, still retaining sufficient ammonia to supply the output at Hochst.

TABLE III.—SULPHURIC ACID (METRIC TONS 100 PER CENT ACID PER DAY)

	1914	1918
Leverkusen.....	340	470
Hochst.....	224	280
Ludwigshafen.....	275	410
Weiler-ter-Meer.....	48	60
Total.....	887	1,220

Meister, Lucius & Bruning have also erected a large new plant at Hochst which has not yet started and was not examined.
The Bayer Co. has erected at Dormagen a large vitriol plant equal to 250 tons per day.

TABLE IV.—CHLORINE (METRIC TONS PER DAY)

	1914	1918
Leverkusen.....	7	20
Hochst.....	4	8
Ludwigshafen.....	13	35
Total.....	37	63

for instance, at Leverkusen a TNT plant producing 250 tons per month was put into operation in six weeks.

Tables V and VI show the amounts produced in the factories visited.

TABLE V.—HIGH EXPLOSIVES AND INTERMEDIATES

Quantities of intermediates are shown only where these were not converted to finished explosives in the producing works.

Factory	(Metric tons per week)									
	Ammonium Nitrate	Dinitrobenzene	Dinitrotoluene	Trinitrotoluene	Mononitro-naphthalene	Dinitro-naphthalene	Dinitrochlorobenzene	Picric Acid	Trinitroanisole	Hexanitro-diphenylamine
Leverkusen.....	250	250	150	40	600	3				
Dormagen.....	60	75	(1)							
Urdingen.....	60									
Hochst.....	500	140	200							
Ludwigshafen.....	25	50		15	300	35			25	
Oppau.....	200									
Merseburg.....	(7)									
Wiesdorf.....		120								
Schleibusch.....	100		150							

¹ For 3 months only. ² Small. ³ For 1 year.
Other intermediates—Ludwigshafen, sodium benzene sulphonate, 100 tons per week.

Other explosives—Schleibusch, hexanitrodiphenylsulphide, 15 tons per week.

TABLE VI.—PROPELLANT EXPLOSIVES, DETONATING SUBSTANCES, ETC.

Factory	(Metric tons per week)						
	Nitro-cellulose Powder	Diethyl diphenyl-nylurea	Diphenyl-nylamine	Nitro-glycerine	Cordite Paste	Tetryl	Fulminate Lead Azide

Kuppersteg.....	250		21	40	6	7	0.7
Troisdorf.....							
Schleibusch.....			35	75			
Opladen.....			(1) 50	40			
Wiesdorf.....							

Poison gas. At first chlorine and phosgene were the main requirements, but afterward a variety of organic substances were employed, all of which were made by

the factories of the I. G. combination. Many of these substances were new and difficult to prepare, and rapid production was only possible owing to the speed with which the peace organization of the dye factories could be utilized for this purpose. When the government wished to introduce a new gas, a conference of the various firms was held at Berlin to determine how the manufacture should be subdivided in order to use existing plants to the best advantage. For instance, the initial stages of the manufacture of mustard gas were carried out at Ludwigshafen and the final stage at Leverkusen.

Tables VII and VIII show the production of gas and intermediate products in the various factories visited.

TABLE VII—OUTPUT OF FINISHED POISON GASES FROM VARIOUS WORKS

Factory	Monthly Average	Output (Metric Tons) Maximum	Total Production (if known) Tons	Date of Commencement
1. Chlorine	Leverkusen... 600	...	...	Prior to war
	Hochst... 240	...	...	Prior to war
2. Phosgene	Ludwigshafen... 860	1,261	18,600	Prior to war
	Ludwigshafen... 288	621	10,682	Prior to war
3. Diphosgene	Leverkusen... 300	...	...	June, 1915
	Hochst... 139	266	3,610	Sept., 1916
4. Chlorpierin	Leverkusen... 200	...	...	July, 1916
	Hochst... 45	101	1,127	Aug., 1916
5. Xylol bromide	Leverkusen... 60	...	...	Mar., 1915
6. Bromoacetone	Leverkusen... 20	...	...	July, 1916
7. Bromoethylmethylketone	Hochst... 19	45	685	Apr., 1915
8. Phenylcarbamylamine chloride	Hochst... 65	124	721	Mar., 1917
9. Mustard gas	Leverkusen... 300	...	4,500	Before July, 1917
10. Diphenylchlorarsine	Hochst... 150	300	3,000	May, 1917
	Hochst... ..	...	...	Feb., 1918
11. Ethyldichlorarsine	Hochst... 78	150	1,092	Aug., 1917
12. Dichloromethyl ether	Hochst... 26	51	253	Sept., 1917
13. Dibromomethyl ether	Hochst... 7	29	69	Apr., 1917

¹ Estimated from capacity of plant. Probably the same quantity was produced at some other factory, as the output of thiodiglycol from Ludwigshafen would suffice for this.

TABLE VIII—OUTPUT OF INTERMEDIATE PRODUCTS FOR POISON GAS MANUFACTURE

Finished Gas	Intermediate Products	Total Output (Metric Tons)	Place of Production	Destination of Intermediate Products
Phenylcarbamylamine	Phenyl mustard oil	(1)	Kalle	Hochst
Mustard gas	Thiodiglycol	7,026	Ludwigshafen	Leverkusen and 1 other factory
Diphenylchlorarsine	Phenylarsenic acid	1,600	Ludwigshafen	Unknown
	Diphenylarsenic acid	1,200	Kalle	Unknown
		4,800	Leverkusen	Probably A. G. F. A., Berlin
Ethyldichlorarsine	Ethylarsenious oxide	840	Ludwigshafen	Hochst

¹ Not obtained.

Note.—In addition Hochst produced 3,000 tons of diphenyl chlor- and cyan-arsines from own intermediates.

MILITARY IMPORTANCE OF THE GERMAN CHEMICAL INDUSTRY

These figures for the output of explosives and gas show the great military value of the factories of the I. G. combination. Although no arrangement had been made to mobilize them at the outbreak of hostilities, they were rapidly converted to war purposes, thanks to their highly trained personnel and the great technical resources of their peace organization. In the future it is clear that every chemical factory must be regarded as a potential arsenal, and other nations cannot therefore submit to the domination of certain sections of chemical industry which Germany exercised before the war. For military security it is essential that each country should have its chemical industry firmly estab-

lished, and this must be secured as one of the conditions of peace, as otherwise we are leaving Germany in possession of a weapon which will be a permanent menace to the peace of the world.

The key to Germany's war production of explosives was the Haber process for the production of ammonia from atmospheric nitrogen. It is significant that large-scale production by this process only began at the end of 1912, and that in the early part of 1914 great pressure was put on the Badische Co. to increase its output. During the war, owing to the extension of the Haber plants at Oppau and Merseburg, Germany has become independent of foreign countries for her supplies of ammonia and nitric acid, substances indispensable for the manufacture not only of high explosives but also of fertilizers for food production. Without such a process Germany could not have made the nitric acid required for her explosives program, nor obtained fertilizers for food production after the supply of Chile saltpeter had been stopped by the blockade, and it is probable that she could not have continued the war after 1916. In the event of another war we might be cut off from supplies of saltpeter.

The resources of the German dye industry are of no less military importance. Most of the gases employed toward the end of the war were complex organic substances, none of which had been made previously except in small quantities, and some of which were prepared for the first time during the war. Gas warfare will undoubtedly continue to develop in this direction, and in the future organic substances will be employed which we do not know today. The use of gas will always offer great opportunities for surprise in military operations, and the experiences of the present war have shown that rapid production of a new gas is essential if the surprise is to be effective. Any country without a well-developed organic chemical industry will be severely handicapped in this respect.

Re-employment Problems and Methods

ALTHOUGH the Victory Loan supplied the funds necessary to bring the boys from France, many of the returned soldiers, sailors and marines have experienced great difficulty in finding their places once more in the business world. This is especially true of young men who left college to enter the service and who now find it impossible to finish their courses, for financial or other reasons. In seeking employment, they find that the other men who have completed college courses have the preference and command the higher salaries, and yet in order to insure decent living conditions for themselves and their families, they feel that they must ask as much as the other men. They do not always get it, and for this reason an appeal is made to the employer of college-trained men to give men of this type a chance to make up in the plant or in the office the time lost while in service—to pay them a living wage during this period and to consider any resulting additional expense as an investment in the nature of a final Liberty Loan. These men made good Over There, and all that they ask now is the opportunity to show that they can do the same over here!

According to Mr. F. A. Giffin, in charge of the Placement Division for Executive, Professional and Technical Men of the Re-employment Bureau of New York City,

the problem of the inexperienced college man, as outlined above, is the greatest one with which the Technical Division has had to contend and yet one which may be easily solved, if employers will again show the spirit which made the Liberty Loans so successful.

The Re-employment Bureau of New York City was organized in April, 1919, to centralize all employment work for ex-service men in New York City. It has developed into a wonderfully efficient organization for bringing together the man and the job. The work is under the jurisdiction of the Re-employment Committee, of which William Fellowes Morgan, president of the Merchants Association, is chairman, and two advisory councils: the United Council of Re-employment, composed of representatives of seventeen welfare organizations and employment services, and the Employers' Council, composed of representatives of eighty-two commercial and trade organizations in Greater New York. The Bureau, which is under the immediate direction of Major Warren Bigelow, is divided into the following departments:

The Procurement Division has charge of obtaining sufficient jobs and of caring for unsolicited jobs which come in either by mail or by telephone.

The Registration Division has charge of registering the applicants and obtaining the information necessary for the Placement Division, and also classifying and routing the applicants to the proper placement sections, as well as filing cards and records of applicants and those who have obtained positions through the Bureau. The Registration Division has registered about 27,000 men.

The Vocational Division, which is a unique feature of the Bureau, endeavors to guide unskilled workers into trades which are not overcrowded and which will offer them a future.

The Placement Division consists of three main sections: General Placement, with eleven classified subdivisions such as, general labor, skilled mechanics, disabled men, salesmen, office clerks, etc.; Recruiting for Army, Navy, Marines, Air Service, Motor Transport Corps and the Shipping Board; Placement for Executive, Professional and Technical Men.

The last mentioned section takes care of all mental workers who receive \$1500 a year or over. About 12 per cent of the total registrants are referred to this division, i.e., about 200 per week. Of these, approximately 20 per cent are placed, 50 per cent find positions themselves or through some other agency or go back to their old jobs, while the remaining 30 per cent accumulate. (About 40 per cent of this class, which numbers over 700 at the present time, belong to the group of young college men referred to earlier in this article.) This division has placed over 500 men with an average salary of \$35 per week at a cost of \$9-\$10 per placement. The men registered range from privates to lieutenant-colonels and some have been placed in positions paying as high as \$25,000 a year. It is estimated that 95 per cent of the men placed stick to their new positions.

There is a great demand for skilled technical men, especially senior mechanical and electrical engineers, since the supply of graduate engineers has been shut off by the war. However, there is an oversupply of junior engineers and there is practically no demand for civil engineers, so that many of the latter are giving up their profession and entering a business career. Increased

activity in proposed construction work was first shown by the extraordinary demand for architectural draftsmen and later for structural draftsmen, concrete and steel designers.

Another problem is the placement of professional men, particularly lawyers and physicians, who have lost their practice while in service or who desire to change to some other line of work. Many physicians have expressed themselves as unwilling to return to the practice of medicine.

A summary of the work done by the Bureau as a whole from the date of organization until Aug. 25 shows that 27,000 men have been registered, 15,200 have been placed at an average cost of about \$5 per placement and that 66,000 positions have been registered by the Procurement Division.

Although the Army will be practically completely demobilized by the end of September, the Bureau has learned from experience that it takes from four to five weeks for the ex-service man to reach the Bureau after discharge and from two to three weeks more to place him, so that the work of the Bureau will in all probability continue until the first of November.

Philadelphia Meeting of the American Chemical Society

The fall meeting of the American Chemical Society will be held at the Bellevue-Stratford Hotel, Philadelphia, Pa., under the auspices of the Philadelphia Section, from Tuesday, Sept. 2, to Saturday, Sept. 6, inclusive. The Philadelphia Section, situated as it is so near the center of our chemical activities, is planning an extensive and unusual program.

The Rubber Division holds its first meeting and a Dye Section is to be established which will function as a separate section this year. The Industrial Division—organized in New Haven in 1908 for chemists in industrial research laboratories, for consulting chemists and chemical engineers and for business executives who find it profitable to keep in touch with the developments in applied chemistry—will hold a symposium on refractories organized by Dr. A. V. Bleining of the Bureau of Standards. A discussion will also be held upon Dr. B. C. Hesse's open letter concerning annual patent renewal fees for the United States.

The Chemical Warfare Service and the chemical fraternity Alpha Chi Sigma have planned reunions in conjunction with the meeting.

Among the many interesting papers to be read at the general and divisional meetings the following may be mentioned:

General Meeting.—"Stream Pollution and Its Relation to the Chemical Industries," Earle B. Phelps; "The Building of Atoms and the Periodic Systems," W. D. Harkins.

Rubber Division—"The Action of Certain Organic Accelerators in the Vulcanization of Rubber," G. D. Kratz, A. H. Flower and Cole Coolidge; "Reactions of Accelerators During Vulcanization," C. W. Bedford and Winfield Scott; "The Effect of Organic Acceleration on the Vulcanization Coefficient," D. F. Cranor; "The Effect of Compounding Ingredients on the Physical Properties of Rubber," C. Olin North; "The Manufacture and Use of Crimson Antimony," J. M. Bierer; "Research on Zinc Products for the Rubber Industry," P. R. Croll and I. R. Ruby.

Division of Physical and Inorganic Chemistry.—"A Slide Rule for Special Cases," F. C. Blake; "The Catalyst in the Oxidation of Ammonia," G. A. Perley; "A Metal to Glass Joint and Some of Its Applications," E. C. McKelvy and C. S. Taylor.

Division of Industrial Chemists and Chemical Engineers.—Report on the Production of Synthetic Organic Chemicals

in the Research Laboratory of Eastman Kodak Co., 1918 and 1919. C. E. K. Mees; Symposium on Refractories, A. V. Bleining, Chairman; "The Classification of Refractories," G. H. Brown; "Work of the Technical Department of the Refractories Manufacturers' Association," R. M. Howe; Symposium on Annual Patent Renewal Fees with the Division of Pharmaceutical Chemistry and Section of Dye Industry, E. J. Prindle, Chairman; "Carbon Black—Its Properties and Uses," lantern, G. St. J. Perrot; "Adherent Rust as an Accelerator in the Corrosion of Iron and Steel," lantern, W. D. Richardson; "Some Properties of Commercial Silicate of Soda," J. G. Vail; "The Leaching of Zinc Chloride from Treated Wood," Ernest Bateman; "Tensile Strength of Glue," G. Hopp; "A New Illuminator for Microscopes," third paper, A. Silverman; "The Extraction of Potash Salts From Kelp Charcoal," by title, J. W. Turrentine and P. S. Shoaff; "Kelpchar, a New Decolorizing Carbon Prepared as a By-Product in the Extraction of Potash From Kelp," by title, J. W. Turrentine, P. S. Shoaff and G. C. Spencer.

Fertilizer Division.—"The Conservation of Nitrate of Soda in the Chamber Process for the Manufacture of Sulphuric Acid," Andrew M. Fairlie; "The Caking of Sulphate of Ammonia," C. G. Atwater and J. F. W. Schnultz; "The American Potash Industry," R. O. E. Davis.

"American Storax" From the Red-Gum Tree

A gum which is in demand by the manufacturers of perfumes, tobacco, adhesives and pharmaceutical preparations is produced by the red-gum tree (*Liquidambar styraciflua*) of the South, though few owners of this tree apparently are yet aware that the gum has any commercial value. The properties and composition of this "sweet gum," as it is called, are similar to those of Oriental storax, obtained from a tree (*Liquidambar orientalis*) which grows in Asia Minor. Cinnamic acid and cinnamic alcohol are two of its valuable components.

Because the war curtailed the supply of the imported product, the U. S. Forest Products Laboratory this season undertook some co-operative experiments to develop methods of gathering "sweet gum" or "American storax." Although the yield of gum from each tree is not large, a price of \$2 or more a pound has made its collection attractive to many individual operators, and a considerable quantity has been put on the market.

The laboratory experiments will be completed in November, and it is hoped that they will provide some cost data which will indicate to what extent "American storax" can profitably compete with the foreign product when normal conditions return.

United Engineering Society Resolutions Relating to Andrew Carnegie

Andrew Carnegie's death Aug. 11, 1919, at Shadow Brook, Lenox, Mass., brought to its close a career which greatly advanced all the engineering arts and sciences. By the introduction into the United States of the bessemer process for the production of steel and by the establishment and development of steel plants which became the greatest in the world, he made available for engineers the most useful modern material for engineering construction. In the successful conduct of many industrial enterprises he amassed great wealth, the possession of which he became to regard with deep seriousness as a public trusteeship. He devoted himself to the distribution of large portions of his fortune to projects for the benefit of mankind. He distributed his wealth not only in many directions, but also with the exercise of great wisdom based on careful investigation. His munificence provided large funds for the building of a home for the great national engineering societies and many associate societies. He was an hon-

orary member of the American Institute of Mining and Metallurgical Engineers and of the American Society of Mechanical Engineers. He was personally known and loved by many engineers. In view of these facts,

Resolved, That the American Societies of Civil, Mining, Metallurgical, Mechanical and Electrical Engineers, the United Engineering Society and the Engineers Club herein express to the family of Mr. Carnegie and record their sincere appreciation of the great contributions of Andrew Carnegie to the advancement of engineering, and of his friendly assistance in making possible beautiful homes for the Engineering Societies and the Engineers Club, thus fostering the spirit of unity in the profession.

Exports and Imports

The Bureau of Foreign and Domestic Commerce of the Department of Commerce reports for June, 1919:

DOMESTIC EXPORTS FROM THE U. S. BY COUNTRIES

Countries	Caustic Soda		Soda Ash	
	Lb.	Value	Lb.	Value
Greece	78,400	\$2,157

The Export Trade Act

THE numerous requests for copies of the export trade act (Webb-Pomerene law) and the large number of inquiries about it call for the publication of a separate pamphlet¹ by the Federal Trade Commission for the information of those desiring to co-operate in the development of our foreign trade through association formed under that act.

We present herewith the outstanding features of this pamphlet.

A complete reprint of the Webb-Pomerene law (Public 126, 65th Congress) is given, together with such sections of the Sherman act, the Clayton act and the Federal Trade Commission act as are referred to in the Webb act. Five pages are devoted to a discussion of the act, including a summary of the law, a discussion of requests for rulings and a list of all organizations that have filed papers purporting to be under section 5 of the Export Trade act. One of the difficulties which exporting houses seem to find with the law is that export companies usually do both an export and import business, while the law provides that its protection is given to associations entered into for the sole purpose of engaging in export trade and actually engaged solely in such export trade.

PRACTICE AND PROCEDURE

In several instances suggestions have been made as to modification of proposed articles of incorporation, already filed, in order that these associations may clearly come within the provisions of the act. The commission is authorized by this law to make recommendations as to how export associations may conform their business to the law, and, within its powers, it proposes to advance step by step in aid of the export needs of the country. It desires to work constantly in co-operation with those who form export associations and also with those who may consider themselves or the public in any way injuriously affected by the methods and practices of such associations.

Where doubt exists as to whether a given method or practice is proper or not, it would seem advisable that the matter be voluntarily presented to the Commission in the early stages, without awaiting its later discovery and possible correction. The second paragraph of section 5 of the Webb act describes the few formalities as to such procedure.

The Commission has prepared blanks, available on request, for making the first and 1919 annual report which enables an easier compliance with section 5 of the Webb act.

Should it become necessary for an export association or for others engaged in the export trade to seek the enforcement of the Commission's power to prevent unfair methods of competition under section 4 of the Webb act the rules of practice do not require formalities in the filing of information or the lodging of complaints, but it is worth remembering that the fuller and more exact the information and references as to proof thereof the speedier the results before the Commission. This is especially true where the charges come from foreign countries where the time necessary for transmission might render the case academic through the sheer lapse of time. Where allegations come from abroad the pro-

cedure of the Commission can be more quickly set in motion if the papers are in such condition as to give the Commission "reason to believe" that alleged facts exist. Copies of letters, advertisements, exhibits and affidavits are extremely helpful, as also the names of witnesses and sources of information both in this country and abroad.

As the Commission can proceed on its own initiative, it is immaterial from what source its information is derived, but it is desirable, wherever possible, that for its confidential use the informant be known.

The Commission's investigation of foreign conditions, practices and combinations in foreign countries and its recommendations to Congress thereon will be greatly facilitated by American exporters keeping the Commission informed of their experiences and instances where their export business is restrained or injuriously affected by any matter or in any manner.

The Commission must depend largely for information and facts upon those who are interested in having the Commission correct any tendencies of export associations to artificially enhance or depress prices within the United States or otherwise burden the American public or restrain the commerce of independent competitors.

All mail for the export division should be addressed to the Federal Trade Commission, Washington, D. C., and marked "Export Division."

Government Soon to Make Armor and Heavy Forgings

The new naval ordnance plant at South Charleston, W. Va., is now about to begin the manufacture of armor plate and forgings for guns of large caliber, entirely new lines of work for Government plants. The South Charleston plant is a \$19,000,000 enterprise occupying more than 200 acres of land. It will be ready for making armor and heavy forgings as soon as the assembling of the necessary working force can be completed. Disturbed labor conditions incident to the war have been responsible for a delay in getting this work started. The new plant is equipped with every modern appliance for the manufacture of its specialties, and will turn out annually 50,000 tons of armor plate, guns, projectiles and miscellaneous ordnance forgings.

Engineers, metallurgists and mill and machine shop men will be interested in the positions which are to be filled in the supervisory and subordinate forces. The United States Civil Service Commission has announced for this plant the need of a superintendent of melting shops at \$5000 a year, a superintendent of forge shops at \$5000 a year, foreman of heat treatment of armor plate at from \$10 to \$14.40 a day, foreman of heat treatment of large guns at from \$8 to \$12.56 a day, foremen of 14,000-ton presses for armor and large-caliber guns at from \$11.84 to \$13.28 a day, foremen of small guns at \$8 a day and foremen of heat treatment of projectiles at \$8 a day. Applicants for these positions will not be given scholastic tests in an examination room, but will be rated on their training and experience, weighted at 90 per cent, and their physical ability, weighted at 10 per cent. Detailed information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or from the secretary of the local board of civil service examiners at the post office or custom house in any of 3000 cities. Journeyman workmen and helpers should apply direct to the labor board at the South Charleston plant.

Metallography of Aluminum Ingot*

Study of the Microstructure of Aluminum Ingot—Influence of Quality of Ingot on the Resultant Castings—"Differential Group Etching," a Phenomenon Noticed in Etching Aluminum—Tentative Explanation of the Differential Etching

By ROBERT J. ANDERSON†

THUS far not much has been written on the metallography of aluminum, although there have been a few isolated papers on micrography of certain aluminum alloys. The microstructure of aluminum ingot has not been described, so far as the writer is aware. Hence information on this subject may be of interest to the light-alloy industry in particular and to metallographers in general. During the course of an investigation now being made by the Bureau of Mines in the metallurgy of aluminum, it became desirable to examine aluminum ingot in order to ascertain whether the quality of the original metal had any effect upon the quality of aluminum-alloy casting made from the metal. The final answer to that question is not yet in hand, but certain aspects of the metallography of ingot have been studied. Most foundrymen in the light-alloy industry are aware of variations in quality of aluminum ingot; therefore a microscopic method for determining quality should be of some value.

In the microstructure of aluminum ingot, a number of peculiarities still require explanation, and the present article deals briefly with some of these. In addition, this article discusses a phenomenon noticed in etching aluminum which, so far as is known, has not been described for other metals and alloys. This phenomenon, termed "differential group etching" by the writer, is so interesting that it seems to be worthy of description. There seems to be a fixed idea that the internal structure of aluminum is extremely simple; as a matter of fact, nothing could be farther from the truth.

PREPARATION OF MICROSECTIONS

The preparation of microsections of substantially pure aluminum is difficult at best; the numerous light alloys are, however, somewhat more easily prepared. Distortion of the surface is to be carefully guarded against, and heavy pressure in grinding and polishing must absolutely be avoided. Aluminum appears to be amorphized quite readily¹ and the production of a relatively thick amorphous surface layer is highly desirable. Hanson and Archbutt² claims that undue distortion may lead to difficulty in etching, since on etching in aqueous solutions the surfaces tend to become covered with a layer of "tarnish" which is troublesome to remove. The section to be examined should be carefully cut out with a hacksaw and then lightly ground flat. This preliminary grinding can be done either with a fine file or by holding the section against a revolving carborundum wheel or a wheel covered with moderately fine emery paper. After this procedure, the section is trans-

ferred to French Hubert emery papers of succeeding finenesses; viz., Nos. 0, 00, 000, 0000. These papers are preferably fastened to wooden blocks and the grinding done by hand. To prevent the emery particles from being forced into the surface of the section, the papers are covered with a film of paraffine or wax. The wax permits a high polish to be given to the section.

For final polishing several methods will yield good results. The writer prefers to polish by hand with a good metal polish on a smooth woolen cloth; the polish will remove the scratches from the No. 0000 paper, and the scratches from the metal polish can be eradicated by rubbing the section on another woolen cloth soaked in water. Final polishing can also be done by using fine tripoli before the metal polish, or by using levigated alumina instead of the metal polish. In any case, the polishing should be done lightly so as not to distort the surface unduly. Hanson and Archbutt³ say they secure excellent results by the use of magnesia powder on a rotating disk covered with a woolen cloth. The disk runs at about 500 r.p.m. They remove the fine scratches from the magnesia by polishing the section then on another disk well wetted with water. The selection of suitable cloth for polishing is very troublesome. The metal polish⁴ used by the writer has been previously referred to, and it has been found to be entirely satisfactory.

ALUMINUM INGOT

For commercial purposes, aluminum ingot is usually divided into two grades; viz., grade No. 1 and grade No. 2. The former contains 99.0 per cent aluminum and over, and the latter from 98.0 to 99.0 per cent. There are also some grades of lower aluminum content, and there is a considerable amount of secondary ingot turned over annually. For vital castings which must meet exacting specifications, the lower grades should not be used. The light-alloy casting industry is mainly concerned with the first two grades. Aluminum ingot appears on the market customarily in two forms; viz., 33-lb. 4-notch bars and 3-lb. 6-notch bars. In spite of the fact that aluminum ingot may contain over 99.0 per cent Al, the physical properties may be very variable. This matter has been definitely proved, and the subject will be more completely dealt with at a later date. The point to be made now is that the chemical analysis as ordinarily carried out is not a complete criterion of quality.

In fact, aluminum ingots of almost identical chemical composition have been found to possess such markedly different physical properties that the analysis has been doubted. The ordinary analysis calls for the determination of copper, iron and silicon, and the difference is said to be aluminum. As a matter of actual fact, this ordinary incomplete analysis is inadequate, gives only a su-

perficil idea of quality, and has been the basis of much fallacious reasoning. These and other matters in the metallurgy of aluminum are important and interesting, but the merest mention must suffice here.

MICROGRAPHY

Aluminum, being a metal of relatively low freezing point, has a quite large grain size; moreover, pronounced difference in microstructure may be found in different ingots of the same approximate chemical composition. Not only is that true, but marked differences in microstructure may be observed in various parts of any single ingot, and peculiar etching characteristics have been observed even in single microsections. Realizing the

FIG. 17. SKETCH OF 33-LB INGOT; CROSS-SECTION; HALF SIZE; SHOWING POSITIONS FROM WHICH MICROSECTIONS WERE CUT

significance of the facts just stated and taking into account the care which must be exercised in preparing microsections, it is not difficult to see that the correct interpretation of aluminum micrographs becomes a rather complicated affair. As has been pointed out previously by the writer, aluminum metallography is in its embryonic stage, and the metal has not yet been subjected to careful microscopic scrutiny by many observers. No doubt a metallography for aluminum will be evolved in time, and that will serve a useful purpose to the light-alloy industry.

To consider for a moment what the quality of aluminum ingot means to the foundries; the practical foundry-

man wants to know definitely whether the quality of the ingot has anything to do with the quality of the resultant alloy castings. There has unfortunately been a good deal of loose talk on this question; actual corroborative tests have been carried out in only a few isolated instances. For the present, it is sufficient to state that the quality of the ingot assuredly does have some influence on the quality of the resultant castings.

Turning now to a description of the microstructures of certain samples of ingot, reference may be made to Table I and to Figs. 1 to 16, inclusive. Fig. 1 illustrates the average structure of sample No. 1; this was a sample of good tough virgin aluminum. The microstructure is allotriomorphic, and the impurities unless in solid solution are mainly at the grain boundaries. Fig. 2 is the same section at another place; the variation in

TABLE I

Kind of Ingot	Physically Called	Sample Number	Chemical Composition				
			Cu	Fe	Si	Mn	Al*
Six-notch	Tough	1	0.16	0.37	0.33	Trace	99.14
Six-notch	Brittle	2	0.28	0.72	0.84	0.02	98.14
Six-notch	Brittle	3	0.18	0.40	0.38	0.04	99.00
Four-notch	Tough	20-1 to 20-5	0.20	0.57	0.18		99.05

* Aluminum by difference.

microstructure within a single section is shown by comparing these two micrographs. Fig. 3 shows the structure of sample No. 2, and Fig. 4 is another micrograph of the same section. The differential etching of groups of dendrites and grains in sample No. 2 is also shown by Figs. 3 and 4, and this matter will be dealt with more completely in a later paragraph. Figs. 5 and 6 show the microstructure of sample No. 3. Samples Nos. 1, 2 and 3 were cut from the center of separate notches of 3-lb. 6-notch ingots. Examination was also made of sections cut from the webs of the same ingots, and the microstructures were reasonably similar.

In studying the microstructure of a 33-lb. 4-notch ingot, a section 0.75 in. thick was cut through one of the notches as shown in the sketch in Fig. 17 and the photograph in Fig. 22. The sketch indicates the various positions from which the microsections were taken. Fig. 7 shows the average structure of sample No. 20-1, while Fig. 8 shows considerable foreign occluded matter, pre-

sumably aluminum oxide; the latter micrograph was taken at a point near the pipe. Fig. 9 gives another aspect of sample No. 20-1, and incidentally it also shows differential group etching. Fig. 10 is a micrograph of sample No. 20-2, showing intergranular occluded matter. Fig. 11 is a micrograph of sample No. 20-3. Fig. 12, also taken from sample No. 20-3, may be compared with Fig. 11 for the purpose of showing the variation in microstructure in different parts of a single microsection; Fig. 11 was taken from about the center of the section, but Fig. 12 was taken at a point near the X edge. Samples Nos. 20-4 and 20-5 were contiguous to the chill mold into which the ingot had been poured, and the effect of chill was to cause a tendency toward a dendritic structure on the X edge of these samples. Otherwise, the microstructures were not dissimilar to those already described for samples Nos. 20-1 to 20-3. All the above micrographs were of sections etched with hydrofluoric acid. A few micrographs of sections etched with sodium hydroxide are shown in Figs. 13 to 16 inclusive; these are self-explanatory and may be compared with Figs. 1 to 6 inclusive.

MACROGRAPHY

The examination of microsections of metals and alloys under low powers often yields very instructive results, and it has proved valuable in the study of aluminum ingots. For low-power examinations, the microsections were prepared in the usual manner, and after suitable etching were photographed. Figs. 18 to 21 inclusive are photographs at seven diameters of samples Nos. 1, 2, 3 and 20-3 respectively. Some idea of the relative grain size can be obtained from the macrographs. Those familiar with the interpretation of macrographs might assume that the differently shaded areas in Figs. 19, 20 and 21 are individual grains of large size. Microscopic examination, however, proves that this is not the case. Each of the presumed large grains is found to have a secondary internal structure, and is made up of a number of small grains or dendrites as the case may be. This brings the discussion to a consideration of differential group etching, but before dealing with that it will be better to consider first some other aspects of aluminum ingot; viz., surface appearance and fractures.

Ocular examination is useful in determining roughly the quality of aluminum ingot. In the foregoing, it has been hinted that the quality of ingot is rather variable

and that the physical properties may be quite different in ingots of approximately the same chemical analysis. In Table I, samples have been characterized as tough and brittle, and these terms are used to describe the behavior of the metal in tensile and bending tests. Without going into the matter in exhaustive detail, a distinction between brittle and tough ingot may be made. The tough ingot usually has greater ultimate strength, yield point, elongation and reduction in area than brittle ingot; further, the former will perform better in the bend test, where, for example, a 0.25-in. machined test piece, 2.0 in. long, is bent on itself. Tough ingot may bend 180 deg. and brittle ingot less than 90 deg. As to surface appearance, the brittle ingot is characterized by a rough, pebbly, whitish, frosted surface, and there may also be cracks in the webs pointing to hot shortness. Tough ingot, on the other hand, is smooth, bright and metallic in appearance. Photographs in Figs. 23, 24 and 25 show the upper surfaces of samples Nos. 1, 2 and 3.

FRACTURES

Fractures of aluminum ingot do not generally furnish interpretable data, but may be useful in some cases. Where fractures of patently brittle and tough ingot are compared, the former are characterized as coarse and the latter as fine. Fractures through the webs of samples Nos. 1, 2 and 3 are shown in Figs. 26, 27 and 28. Fig. 29 shows the fracture through one of the webs of the 33-lb. ingot from which samples Nos. 20-1 to 20-5 were taken. In the case of the fractures of samples Nos. 1, 2 and 3, these were effected by bending a 6-notch ingot through one of the center webs until fracture occurred. Sample No. 1 bent through practically 180 deg.; samples Nos. 2 and 3 broke off sharply at about 10-15 degrees.

ETCHING REAGENTS FOR ALUMINUM

The most commonly used etching reagents for substantially pure aluminum are hydrofluoric acid and sodium hydroxide, both in aqueous solution. The con-

FIGS. 23, 24 AND 25

Upper surfaces of samples: 1 (upper); 2 (center) and 3 (lower)

FIGS. 26 TO 28

Fractures through the webs of samples 1, 2 and 3 respectively

centrations may vary widely within limits, but 5.0 to 10.0 per cent solutions of hydrofluoric acid and 10.0 to 20.0 per cent solutions of sodium hydroxide will be found most useful. When it becomes necessary to clean and brighten an etched surface, momentary immersion in concentrated nitric acid, sp.gr. 1.42, or in concentrated chromic acid is recommended.

CONSTITUENTS OF ALUMINUM

The common impurities found in aluminum ingot are copper, iron and silicon. Copper forms a solid solution with aluminum to the extent of several per cent Cu; iron forms the compound FeAl_3 , which is practically entirely insoluble in the solid state, and silicon occurs quite often as elemental silicon. Silicon and FeAl_3 can be distinguished from each other in unetched samples by the gray tone of the silicon as contrasted with the white of the FeAl_3 . They are more conveniently distinguished by etching with hydrofluoric acid, when the FeAl_3 will be seen dark and the silicon lighter. Sodium hydroxide also attacks FeAl_3 , but silicon appears to be attacked with difficulty by either of these reagents. Hanson and Archbutt¹ have recently described methods for differentiating these constituents, and no further elaboration is deemed necessary here.

ETCHING CHARACTERISTICS OF INGOT

Differential group etching of aluminum has already been mentioned. This is shown admirably by the low power macrographs and better by panorama micrographs. Owing to the large amount of space necessary to reproduce a panoramograph, it is not considered advisable to attempt to show one, but a short description will be given and a few selected single micrographs shown. As stated above, it might appear from a cursory examination of the macrographs in Figs. 18 to 21 inclusive that each differentially etched area represents a single grain or possibly two or three grains oriented nearly the same. On the contrary, this is not so at all; as a matter of actual fact, each presumed large grain has a secondary structure and is made up of numerous smaller grains or dendrites. This group etching of grains has also been observed in some aluminum alloys as well as in substantially pure aluminum. It seems that

each group of grains which reflect light similarly into the tube of the microscope is similarly oriented while those of a neighboring group are differently oriented. This means simply group orientation of grains, the orientation changing from group to group. Whether this is actually so or not is not known to the writer, but it would appear to be.

The phenomenon may be observed fairly well in micrographs. In Fig. 14, there is a group of four grains reflecting the same amount of light, surrounded by grains reflecting different amounts of light. In Fig. 15, the line of demarcation from one group dendrite to another can be plainly seen. Other micrographs, Figs. 4, 5 and 9, also illustrate this feature. For the time being, the phenomenon may be referred to as "differential group etching" for want of a better descriptive title. Figs. 30, 31 and 32 are micrographs of sample No. 2 after fairly deep etching with hydrofluoric acid. These are at different positions on the microsection. When properly fitted together and matched, a series of photomicrographs across the entire surface of a microsection gave a sort of panorama of the surface from edge to edge.

Fig. 30—Sample 2, at edge. Fig. 31—Same as Fig. 30, but at another place. Fig. 32—Same as Fig. 30, but at another place. All $\times 75$. All etched with HF

Now, with regard to an explanation of the differential etching, it is the opinion of the writer that a possible tentative explanation may be as follows: When aluminum freezes, it normally freezes so as to form relatively large grains of the approximate size indicated by the groups. With no impurities present, the large grains would represent the true grain size. All the crystalline aluminum, surrounded by its amorphous phase together with part of the impurities, in any one so-called group is oriented the same throughout; all the crystalline aluminum in the next adjoining group is oriented differently. Part of the eutectic-forming impurities are not rejected to the boundaries of the large grains represented by the groups, but are scattered through each large grain. At the moment of final freezing, i.e., when the temperature is so low that no impurities can be liquid, these impurities freeze in position (wherever they happen to be) and thus give rise to a structure within each large grain. Where the impurities form a continuous network, they give rise to smaller grains, and where they are discontinuous, they result in the formation of stringers. The same argument applies to the different orientation of groups of dendrites. An objection which may occur to some is that the phenomenon may be simply due to a stain or tarnish on the surface; this cannot explain the case, because no stain would follow grain boundaries sharply, but would appear as an indiscriminate pattern.

International Union of the Associations of Pure and Applied Chemistry

The Interallied Chemical Confederation, which was organized in Paris last April, held its second meeting in London July 14-18. At this meeting the delegates were:

Belgium—R. Lucion, ex-president of the Société Chimique de Belgique; J. Timmermans, professor at the University of Brussels.

France—A. Behal, Member of the Academy of Medicine, professor Ecole Supérieure de Pharmacie; J. Gerard, chemical engineer, general secretary of the Société de Chimie Industrielle; P. Kestner, president of the Société de Chimie Industrielle; Ch. Marie, general

secretary of the Société de Chimie Physique; R. Marquis, editor of the *Bulletin de la Société Chimique de France*; Ch. Moureu, president of the Interallied Council, and of the French Federation of the Chemical Associations, professor at the Collège de France.

Great Britain—F. Frankland Armstrong, member of the Council of the Society of Chemical Industry; Henry Armstrong, emeritus professor of chemistry in the Imperial College of Science and Technology, past president of the Chemical Society; A. Chaston Chapman, past president of the Society of Public Analysts; Henry Louis, professor of mining and metallurgy in the University of Newcastle-on-Tyne, past president of the Society of Chemical Industry; Sir William Pope, professor of chemistry in the University of Cambridge, chairman of the Federal Council of Pure and Applied Chemistry, past president of the Chemical Society; W. P. Wynne, professor of chemistry in the University of Sheffield, president of the Chemical Society.

Italy—G. Pirelli of the Society of Chemical Industry, Milan; Dr. Severini of the General Cyanamide Society.

United States and Canada—Frederick Cottrell, chief metallurgist U. S. Bureau of Mines; Prof. Charles L. Parsons, chief chemist U. S. Bureau of Mines, secretary of the American Chemical Society; Edward W. Washburn, professor of ceramic chemistry, University of Illinois; Robert J. Ruttan, director of department of chemistry, McGill University, Montreal, president of Royal Society of Canada, member of Advisory Council for Scientific and Industrial Research.

The meeting was devoted to the detailed elaboration of the policies and aims of the confederation.

It has been decided that the official name of the Confederation shall be henceforth "Union Internationale des Associations de Chimie Pure et Appliquée" (International Union of the Associations of Pure and Applied Chemistry), and that the provisory business address shall be 49 Rue des Mathurins, Paris.

The following officers were elected: President, Prof. Moureu; vice-presidents, Chavanne, Parodi Delfino, Charles L. Parsons and Sir William Pope; general secretary, Jean Gerard.

The next meeting will be held in Rome in June, 1920.

¹See CHEM. & MET. ENG., Vol. 20, No. 11, June 1, 1919, p. 561.

The Design of Electric Furnaces

Consideration of the Elements of Size and Other Details in the Relation to Operation and the Recovery of Metal, With Special Reference to the Production of Ferromanganese

By R. C. GOSROW

A CERTAIN article in the Dec. 1 issue of CHEMICAL & METALLURGICAL ENGINEERING referring to the size of ferromanganese furnaces, and the relation of size to manganese recoveries, touches a subject which is a principal factor in the successful and profitable electric smelting of manganese ores. Such ores may be carbonate, oxide or silicate ores of manganese. Successful and profitable electric smelting refers to the production of a useful alloy of the iron-manganese series for steel manufacture, and other uses; and obtaining sufficient recoveries of the metal from the raw ores as to give a reasonable margin of profit on the operations, from the marketing of the alloy. By any method of obtaining increased recoveries of metal from the ores, it is reasonable to anticipate increased returns from the operation.

The subject first referred to has been so stated that a certain "size of furnace" is considered to be an important factor in obtaining increased recoveries of metal from ores. This is undoubtedly very true, but ambiguous. "Size of furnace" must consider three physical dimensions primarily: length, width, depth. Or more strictly speaking, "height of ore column" should be used in place of "depth." "Size" may imply cubical volume, also any component which may be a factor in its volume. It may also suggest the electrical capacity in transformers connected to the furnace; or it may mean the alloy or metal output. Thus it may be seen that "size" of furnace is rather a meaningless expression.

Two furnaces may have exactly the same cubical contents. One may have a variable in some component of its cubical measure, as compared with the other, and yet both furnaces will not operate efficiently on the same voltage, or respond equally to the same charge. The two furnaces may not develop the same conditions during operation; will not carry the same load; will not operate equally well on the same or equal voltages; and will not produce the same slags, or metals, according to the analytical comparisons. Neither will each furnace produce the same tonnage, providing both have equal electrical connected capacities. I mention these points initially to outline the absolute necessity of analyzing and comparing each dimensional component of the furnace design, and not merely to take the summation or product of all dimensions, and alone compare smelting operations on furnaces of equal holding capacity, or of equal electrical connected capacity.

RELATION OF FURNACE SIZE TO EFFICIENCY

In paragraph 1 of the article referred to, on page 749, the author states that "observation of a number of electric furnaces, varying considerably in size and

transformer capacity, and all working under the same conditions, shows the small furnace to be much more efficient in operation than the large furnace."

After reading the above statement, the question one would ask is, "Why is the small 'size' of furnace more efficient in operation?" Is the efficiency referred to rated on the kilowatt-hour consumption per ton of metal of standard content produced, or on manganese recovered in the alloy? It may be both. A low kilowatt-hour consumption may go hand in hand with a high recovery of metal, and vice versa. A low recovery of metal means larger slag volume and greater tonnage of ore to be put through the furnace to keep up the production, increasing power consumption considerably per ton of salable alloy produced.

ADVANTAGES OF "SMALL SIZE" FURNACE

As the "small size" furnace is more carefully charged than the "large size" furnace, the charge may be better distributed over the top area of the furnace, and be given more stoking, if such be necessary. As the charge is weighed in less quantity, more careful weighing may be accomplished. Also with the lesser weights of charges, and mixing of charge ingredients, errors in weighing cause greater fluctuations in smelting operations.

Usually mechanical features of strength require greater electrode areas than the actual load requirements of the furnace would specify. This means better heat distribution, and less current density in the electrodes, with less voltage drop in the electrodes. By increasing electrode areas, increased water cooling in the holders may be accomplished, directly keeping the electrodes cooler above the charge line.

As the "small size" furnace can be better manipulated, a faster furnace results, with increased efficiency and economy in operation over a slower furnace. With a small crucible the furnace may be more thoroughly drained of metal at taps, and slag and carbide accretions controlled and readily removed.

The remarks here made that are relative to a comparative "small size" of furnace do not in any way validate these points and establish them. Frequently operations cannot bear a number of small units and their increasing number alone would eliminate them as a commercial factor. Larger units in equipment frequently solve a problem not only of metallurgy but of finances. Larger units where successful are much desired to small units.

CAN LARGE FURNACES BE EQUALLY EFFICIENT AS SMALL?

The question may now justly be put, "Why cannot the 'large size' furnace be equally efficient, metallurgically, electrically and from a dollars-and-cents viewpoint, as the 'small size' furnace?"

It must be considered that, "large" and "small" being

¹"Size vs. Recoveries in Ferromanganese Furnaces," E. S. Bardwell, CHEM. & MET. ENG., Vol. 19, No. 11, p. 749, Dec. 1, 1918.

comparative adjectives, it would be more to the point to describe two furnaces for comparison as being "twice the length," "one-half the depth of ore column," "one-third the width," "one-quarter the volume," etc.; these statements then being based on any dimensional component of the furnace volume: its electrical equipment, electrode sizes and areas and their relation to furnace crucible area, the rate of power input, and metal production, etc.

During the past eight years the writer has been actively and intensively engaged in the electric smelting of manganese, silicon, chromium, tungsten and molybdenum ores for the production of their ferro-alloys, also the electric smelting of iron ores for basic and foundry pig-irons, and has continually made a careful study of the furnace conditions on each, endeavoring to determine those factors which under some instances gave failures, while in others marked success. These conditions were encountered when smelting the various ores and in various designed and proportioned furnaces, with varying electrical capacities. I use the term "proportioned" in preference to "size." It was demonstrated that the proper proportioning of the several dimensions of a furnace, to do certain reduction work on ores by electric heating, must be determined by careful study and observation, and one must build the furnace and equipment into those conditions which exhibit themselves during operations.

EXPERIENCE WITH A LARGE FURNACE

I desire to narrate an experience while operating two 15-ton rated ferromanganese furnaces in 1914. The one furnace was constructed after an ideal, or rather a dream. I use the term "constructed" because the furnace was not "designed," but the structural details were drawn up and the job assembled, with the result that there was on the ground a steel shell brick-lined, electrodes and holders, buses and transformers, and a great variety of electrical paraphernalia. The furnace was erected when I arrived, and it was ready to operate.

The furnace shell was made of 3-in. steel plating, heavily reinforced and braced, and was a good piece of work. The shell measured 27 ft. inside in its length, with curving side walls 12 ft. across at the center, and 10 ft. at the ends; and from the bounding angle around the top of side and end wall plates to the bottom plate approximately 12 ft. 6 in. This was indeed a tank. An 18-in. brick lining was put in all around and an 18-in. bottom. This lining and bottom in the shell gave a crucible of 24 ft. by (average) 8 ft. by 11 ft., having a cubical volume effectively filled with charge of 1900 cu. ft. The four electrodes were 12 in. in diameter Acheson graphite, with threaded cone joints. The transformer installation consisted of six 750-k.v.a. single-phase General Electric transformers, two on each phase connected in parallel. Copper buses and electrode holders were sufficient for maximum loads carried. The electrical equipment on this installation was well laid out, and caused no interference, but it was not possible to get any good measure of this electrical capacity into that furnace full of charge material.

This furnace was considered a "large" size furnace. From the standpoint of smelting capacity it was a "small" size furnace. Here we have two "sizes" for the same furnace, each dependent on particular features of design, production and the ratio of certain component parts to one another, but such statements are vague and ambiguous when speaking of "size."

I wish to analyze some of the details of this furnace:

<i>L</i> —Length inside lining.....	24 ft. 0 in.
<i>W</i> —Width inside lining.....	8 ft. 0 in.
<i>D</i> —Depth of ore column.....	10 ft. 0 in.
<i>V</i> —Cubical contents crucible (effective).....	1920 cu.ft.
<i>A</i> —Crucible area.....	192 sq.ft.
<i>E</i> —Electrode area.....	3.14 sq.ft.

Existing ratios of components:

$\frac{L}{W}$	3 to 1
$\frac{A}{E}$	61.2 to 1
$\frac{D}{W}$	1.25 to 1

Voltage normally carried in buses.....	80 volts
Max. load carried in furnace any time.....	1,800 kw.
Max. load carried per cent of total time.....	11 per cent
Approx. current at 80v., 1800 kw., 0.85 p.f.....	19,100 amp.
Approx. current per middle phase.....	11,000 amp.
Approx. current per end phase.....	5,500 amp.
Approx. current per cubic foot of charge.....	10 amp.
Electrodes connected in delta.....	
Production: three tons per 24 hr.	

From the above figures we may note, the furnace, filled 90 per cent of its effective volume with charge, amounts to 1900 cu.ft. Then from power input we may calculate 10 amp. per cu.ft. of charge, or approximately 10 amp. per 180 lb. of charge. If it were possible to distribute evenly the heating effect of this current throughout the furnace, it can be readily appreciated that a minimum amount of work would be done. The net result would be small volumes of fused charge probably reduced near the electrodes, and large volumes of unfused charge, not melted or reduced, spread throughout the volume of the charge at low levels in the furnace. This anticipated result was verified. In proximity to the electrode tips high temperatures were developed. As the furnace hearth was conducting, the path of least resistance to current flow was straight down to the bottom, consequently rapid and excessive heating occurred in the areas directly under and around the ends of the electrodes. It was therefore only possible to carry loads (electrical) when fused and reduced material made contact between the electrodes and the furnace bottom. The electrodes were spaced 66 in. center to center. This apparently was too great a distance, at the then operating voltage, for a continuous passage of current from one electrode to the next, and to provide a continuous heated path for current to pass from one phase to the next, to give proper phase balancing, and also to develop the temperature for smelting. The conditions, then, represented a molten pool under each electrode, contact with the hearth, passage of current to the next pool through the hearth and to the electrode, completing the circuit as the current travel may be. But areas midway between the electrodes were cold, semi-fused non-conductors, and insulated each electrode, electrically and thermally, from the next.

THERMAL INFLUENCE OF THE ELECTRODE

Here, then, was a phenomenon exhibiting the heating influence which an electrode has over an area affected by it. In order to classify and distinguish this phenomenon I have termed it the "thermal influence of the electrode." I would define the expression as being the effect of the current at the electrode and contact, and the influence which the electrode has in distributing this heat to a surrounding area. This may be determined experimentally for any voltage range, with any nature of materials constituting the charge, and for any power loads, but depends principally on the voltage between the electrode and the charge or the hearth, and the nature of the charge, electrically and physically. With furnace conditions so abnormal that only light and uncertain loads could be maintained in the furnace,

and a low ore column being necessary, the loss from volatilization was certain to be high. Figures from periodic capitulations showed slag and volatile losses of manganese to run from 22 to 32 per cent. These figures show very poor recoveries compared to others on the same ores. The reasons therefor are apparent.

INEFFICIENCY DUE TO IMPROPER PROPORTIONING

The various related dimensions of this furnace lacked the proper proportioning to develop the best efficiencies in the operations. As the results aimed for by a proper mixing of the charge were lost, due to the frozen areas in the furnace, the proper reductions did not take place, accounting for the high manganoous oxide content in the slags. Some of the slags ran as follows:

MnO Per Cent	CaO Per Cent	SiO ₂ Per Cent
28.0	38.7	28.3
22.3	37.9	30.8
27.4	35.1	29.3
27.0	28.5	36.1
24.0	35.8	33.5

These represented weekly averages, and running on irregular operations. These erratic smelting conditions caused high volatile losses, running as high as 9 to 14 per cent. But volatile losses may be controlled only to a moderate figure. It is not possible to reduce them to zero. This furnace was run for 8 days only, and produced 24 tons of 80 per cent ferromanganese alloy. The recovery was 62 per cent of metal. Maximum load for 11 per cent of the time was 1800 kw. Eighty-eight tons of manganese ore averaging 44 per cent Mn and 18 per cent SiO₂ were smelted. This was a "large" size furnace in all respects except production and power input. It had large dimensions only. But this was not its real and only fault. The real and primary cause may be attributed to the design and lack of care and attention to the proper proportioning of its component parts. Such an inefficient piece of apparatus makes a poor but effective comparison.

The second furnace was of similar constructional details, but in its design there were incorporated those metallurgical principles of detail which the apparatus was required to carry out. Careful attention was given to the details of properly proportioning those component parts which were to make up the furnace. It had developed in my experience to regard carefully certain essential ratios in furnace details as all important in the design. I had also observed the effect of electric heating in straight resistance type ore smelting furnaces, and had learned to appreciate the effect of heat caused by the current from one electrode, and heat caused by the current from an adjacent electrode. This particular relationship as before mentioned I have termed the thermal influence of the electrode. This heat influence may be large or small depending of course on the voltage drop between the electrode and the charge or the furnace hearth, the power input and the nature of the materials in the charge. As the mathematical value may be expressed in terms of the electrode diameter, this is primarily a factor. From the value of the thermal influence of the electrode, under certain conditions, we may find a value representing the ratio of electrode area to area of furnace crucible.

AREA OF THERMAL INFLUENCE OF ELECTRODE

To illustrate this statement: It has been determined by observation and measurement that the area of thermal influence of a 12-in. diameter graphitized electrode in an ore smelting furnace, running at 60 v. on

the buses, 1800-kw. load, could be represented by the formula:

$$AT = \frac{(d - a)^2 \times 0.7854}{144}$$

in which

AT equals sq.ft. area of thermal influence of the electrode.

d equals electrode diameter in inches.

a equals a constant; depending on voltage, nature of materials in the charge, etc. For manganese, chrome, and iron smelting this value has been found to be 2.5 to 2.75, and using graphitized electrodes.

The diameter of the area of thermal influence may be also found by:

$$DT = \sqrt{\frac{AT}{0.7854}}$$

Considering the plane of the thermal influence area to be horizontal, it is now possible to determine the proper spacing of the electrodes, and also to fix the area of furnace crucible and the ratio of furnace area to electrode area. We now have a starting point for assembling the several factors entering into the design of the furnace. As the energy consumption per ton of product, and desired production must be known, these factors must be balanced against the former for electrode area and furnace crucible area. The proper spacing of the electrodes is an important feature and directly concerns efficiency of operation in any "size" of furnace. It is primarily essential to have a furnace operate with a cool top and a hot hearth. To obtain this the electrode spacing must be such as to utilize the thermal influence of each electrode at the plane of electrode contact, in the smelting zone of the furnace. Also the electrodes should be sufficiently far apart to increase, as far as possible, furnace capacity for charge. They must also be properly spaced to eliminate any "jumping across" of current from one electrode to another in the upper part of the furnace and in the unsmelted portion of the charge. By considering these factors, electrode spacing will be ultimately fixed.

EFFECT OF DEPTH OF ORE COLUMN

The proper depth of ore column and length of electrode to carry are very important factors, often given little thought and consideration, because their causes and effects are not understood. Many furnaces which I have examined and studied showed no reasons for making these dimensions as they were. The proper depth of ore column must bear a definite relation to the material being smelted and to the metal produced. The height of ore column directly bears the same relation. In smelting chrome and manganese ores lower ore columns are used than are in smelting iron ores. This is due to the difference in reducing reactions and slag purifying of the metal; also in manganese and chrome smelting no well of metal is maintained as in iron smelting.

In the electric smelting furnace, reducing gases are not depended on or utilized for ore reduction in the descending column. But as reduced gases are not utilized for reduction long ore columns are not necessary, and also too short ore columns are not desired. But in the "small" capacity furnace operated by hand, shorter ore columns may be used, because the accumulation of heat on the hearth is not so great as in the "larger" mechanically operated furnaces. We must also be guided by

the mechanical strength of carbon and graphitized electrodes, and the economy of carrying average lengths of either in the furnace.

The depth of ore column may not always be determined solely by metallurgical conditions. The designer may desire to carry a height of ore column inconsistent with strength of electrodes or length of electrodes obtainable from the manufacturers. He must be guided by a combination of conditions.

In the case of graphitized electrodes, good mechanical joints may be made and a joint having at least 85 per cent of the strength of the solid body of the electrode may be obtained. This refers to transverse strength of the joint and the material. Ungraphitized carbon electrodes do not exhibit such good mechanical properties in the joints. The pressure of the charge against the electrodes and the movement in the charge largely determine length of electrode, by gaining the requisite mechanical strength.

RELATION OF FURNACE DESIGN TO LIFE OF REFRACTORY LINING

A most important subject to a smelter is usually linings, pertaining to the life of the refractories in the furnace. The proper design of furnace has considerable effect on refractories, and we have another important component of furnace design. It is the distance from the front and back walls of a furnace to the electrodes (considering the electrodes in a straight line with the furnace long axis). This proper proportioning calls for a close study of past furnace operations on various loads, metals, ores, charges and rate of smelting. My experience has shown that a furnace inner-wall-line should be just close enough to the electrodes as to allow charge to fuse on its surface, but yet be far enough from the electrodes to interfere with fluxing or melting of the wall refractory. This may be controlled to a large extent by using water-cooled wall plates so that the fusing may be stopped by the rapid conduction of heat as soon as this condition is approached. In ferrochrome smelting this practice is of considerable benefit in maintaining the linings. The bad results of having the walls too far away are also numerous. The bad results may be exhibited by a cold tap-hole; running of the unfused charge into the tap-hole at time of tapping metal; inactive charge in the furnace not working down and being smelted, causing scaffolds and hangups; excessive heating of the one wall. On the side of the furnace from which tapping is done, the cooler wall conditions should result from the unfused charge constantly moving on this wall and the charge being shifted when tapping of metal takes place. On the other hand, it may also be the hotter wall, because the hot charge would follow the flow of metal, which would run to the tapping hole or notch. The opposite wall, then, would now exhibit the hotter conditions due to the charge lying dead on this wall.

If the imagination may be used, we can say the following conditions exist: As before stated, each electrode has a certain area over which its heating influence is exhibited. Consider three or four electrodes in a straight line, along the long axis of the furnace shell. Consider the thermal influence areas to be circular or nearly so, as the electrode is circular. We would then have under proper conditions three or four circular (or nearly so) areas, tangent to or interlocking one another; in other words, a hot area continuous through the center of the furnace, due to overlapping of heated areas.

As the thermal influence areas also extend at right angles to the long axis of the furnace, its effect is extended to the front and back walls, and tangents to such areas would be the wall line. The width of the furnace may be so determined, and the ultimate results on the wall refractories may be determined. It must not be considered that the location of front and back walls from the electrodes is as vitally important along the top of the charge. Here no fusion or reduction takes place, but the plane of proper fixing of these distances is in the fusion zone only. But, as will be mentioned later, straight walls are desirable, and not walls giving enlarging or reducing forms to the furnace shell.

DETAILS AND PROPORTIONS OF ANOTHER FURNACE

This second furnace was designed with the consideration of points such as those previously mentioned. It was a "large" size furnace, in cubical volume, in smelting capacity, metal production and power input. I desire to attach some of its details and proportions:

<i>L</i> —Length inside of lining.....	15 ft. 6 in.
<i>W</i> —Width inside of lining.....	7 ft. 6 in.
<i>D</i> —Depth of ore column.....	7 ft. 10 in.
<i>A</i> —Area of crucible.....	116 sq.ft.
<i>E</i> —Area of electrodes (4, graphitized).....	3.14 sq.ft.
<i>V</i> —Cubical contents (charge).....	908 cu.ft.

Existing ratios of components:

$\frac{L}{W}$	2.07 to 1
$\frac{A}{E}$	37.0 to 1
$\frac{E}{D}$	1.04 to 1

Voltage normally carried on buses.....	60 volts
Max. load 95 per cent of the total time.....	1,650 kw.
Transformers, 3 750 k.v.a., delta connected.....	Single phase.
Approx. current at 80 v., 1650 kw., 0.88 p.f.....	24,000 amp.
Approx. current per middle phases.....	14,000 amp.
Approx. current per end phases.....	7,000 amp.
Approx. current per cu.ft. of charge.....	27 amp.
Approx. current per 100 lb. of charge.....	27 amp.
Production: 16 tons 81.5 per cent Mn ferromanganese alloy per 24 hr.	

REPRESENTATIVE ANALYSES OF ORES SMELTED

Oxide and Rhodonite Ores. On Dry Basis	Per Cent
Manganese (metalloid).....	40 to 51
Silica.....	24 to 10
Manganous oxide.....	16 to 9.5
Manganese dioxide.....	52 to 68
Ferric oxide.....	3 to 1.75

SLAGS PRODUCED

High and low manganese contents			
MnO	SiO ₂		CaO
16.3	36.0		41.3
13.55	35.4		44.3
12.1	36.8		44.6
14.3	36.0		44.4
14.4	42.0		40.2
14.25	39.0		41.9
11.8	37.2		45.1
14.6	36.8		41.7

The metal account over a 90-day period showed:

	Per Cent
Manganese in the alloy.....	79.55
Manganese in the slag.....	15.65
Manganese in dust and volatile losses.....	4.80
	100.00

EFFECT OF DESIGN ON HEAT CONCENTRATION

This second furnace, then, both in features of design and in operation, was much superior to the first one. The current density if evenly distributed throughout the furnace calculates to 27 amp. per cu.ft. of charge, while in the first furnace this value showed only 10 amp. This figure, while not being of any great value in this significant use, means considerable when it is considered that every cubic foot of material is acted upon by about two and one half times the current and heat that the first furnace shows. These values must not be taken in their mathematical value, but in their indicative terms. It also gives a fair value for the comparison of two fur-

naces, to arrive at a relation for heat input. In the second furnace there was accomplished a greater concentration of heat, rather than a greater distribution of heat. The value for current density interprets this condition. Even heat distribution and also heat concentration may be accomplished with the proper design of the apparatus and proper proportioning of its component details.

The conditions governing voltage ranges in an ore smelting furnace are not a direct comparison to those encountered in the steel furnaces using arc and arc-resistance heating. The smelting furnace here referred to uses both arc and arc-resistance for the generation of its heat. It may be desired to change the voltage during the operations; this would necessitate variable voltage regulation on the transformers; or it may be desired to use a fixed voltage on the transformers and vary the resistance in the furnace. The subject of the proper voltage for best recoveries and proper operating conditions does not appear to be the question to settle. The question appears to be: With any voltage on the secondary side of the transformer, within reason of the points previously referred to on this subject, what are the conditions which can be obtained to get the best results from the given voltage? The matter of a few volts variation is nothing here nor there. Usually an approximate voltage is determined on to build the equipment to, often determined from some past experience, etc. It is not necessary to pay great attention to voltage range, and to spend large sums of money to build special expensive equipment to get a certain desired voltage. This may and can be taken care of by other means, and the subject of adjusting the furnace conditions to a transformer's secondary voltage may be taken care of. This of course refers to the moderate and not the extreme.

INFLUENCE OF REDUCING MATERIAL USED

In using the various reducing materials—coal, coke, charcoal, petroleum coke, gas carbon briquettes, etc.—and using any one of them in a range of sizes from $\frac{1}{8}$ -in. up to 24-in. ring size, it will be noted that a varying set of conditions exists for varying size of the same material and for each different material. To eliminate unnecessary repetition here, I refer to my article on "Coke as Reducing Agent in the Electric Smelting Furnace," METALLURGICAL & CHEMICAL ENGINEERING, Vol. 14, No. 12, June 15, 1916, Page 691 et seq. Here only two reducing agents are compared, coke and charcoal. But the conditions produced by the use of any of these materials bear directly on furnace operations. Such conditions may be defined as varying voltage by varying the resistance, power efficiency in the furnace, and recovery of metal in the alloy, and manganese content in slags.

It might be stated here that a transformer with the voltage ranges 30-60 or 30-60-90 would meet all requirements on a smelting furnace. A fixed voltage may be used on the secondary buses, and internal resistance of the furnace varied. By a change in the reducing material used, a change in the nature of the charge may be effected, consequently a change in the electrical characteristics of the charge is effected. Also a change in the size of the material effects a change in the electrical conditions.

In one furnace producing ferromanganese, fine coke (1 in.) continually produced carbides, while coarse coke ($2\frac{1}{2}$ in.) gave good reductions and produced a minimum of carbides in the slag, with increased alloy production. Lump charcoal also promoted better conditions. In an-

other instance in producing foundry-pig, 1-in. coke made good foundry-iron (2-2½ per cent silicon). When using coarse 24-in. lumps, a low silicon pig resulted, under 1 per cent silicon. These operations took place in making electric furnace pig iron on 30-ton furnace operations direct from ore in the furnace. The component details of furnace design also played a large part here, as the electrodes were probably too close together, allowed a large part of the current to jump across, and made the furnace top very hot. The fine coke did not exhibit these details, but it caused a very hot furnace and caused the formation of considerable carbide in the bottom of the furnace. These carbide accretions soon built up and caused hang-ups, with the result of burning out side and end walls. Water cooling was resorted to, and while it made considerable difference on the side walls, did not help the interior of the furnace. One reason for the accumulation of these accretions at the point where they did occur was a contraction in the area of the furnace, causing excessive heating to a small volume of charge here and producing compounds of high heats of formation. Restrictions in shape and dimensions are bad features in an electric furnace and should be avoided unless for vital reasons.

COKE AND CHARCOAL IN DEEP AND SHALLOW FURNACES

In two different furnaces running on ferromanganese, having the same bus bar voltages, same ore and reducing material, neither furnace had the same height of ore column, or the same spacing between electrodes. The deeper furnace—9-ft. depth of ore column, 60-in. spacing of electrodes—worked better on coarse coke. The other furnace—7-ft. depth of ore column, 40-in. electrode spacing—worked better on coarse charcoal. From my article referred to this becomes apparent. The shallow furnace worked well on 1-in. coke, while the deeper furnace could not be run on 1-in. coke. By increasing the voltage on each furnace and connecting the deeper furnace in star, the only alternative was a higher ore column. With higher voltages, my opinion leads to the use of higher ore column. Higher ore column means more electrode length to carry, with increased breakages. I once decided to investigate the relation of voltage to electrode breakage, and now believe that high voltage meant high ore column and consequently more electrode breaks. Undoubtedly the resistance of electrode material has something to do with electrode weakness, but in such conditions as an electrode smelting furnace runs under, this would be a minor cause.

Another point which has considerable bearing on furnace operations and recoveries is the method of charging the furnace. As referred to in the beginning of this article, a furnace controlled and worked entirely by hand can be more easily charged than a furnace requiring mechanical appliances for loading and charging. This is of course due to the better manipulation of the charge by the operator. One of the essential conditions to be desired in charging a furnace is to maintain the charge level on top of the ore column. This may be obtained in two ways, one by distributing the material by hand-rabbling, and one by properly spotting or placing the charge when dumping.

ADVANTAGES OF HAND-CHARGING AND RABBLING

The operation of spreading the charge by hand-rabbling becomes increasingly difficult as the areal dimensions of the unit and size of the charges increase. This is apparent. If mechanical pushers are used on the top

of the charge, other mechanical difficulties arise. Also the desirability of performing hand operations on a furnace is of considerable advantage. Most of the charging may be done by a shovel and hand labor. In this way 20 lb. may be the maximum load thrown on the charge at one time and place. This load may be placed exactly where desired. The small unit charges may be well mixed beforehand. The charges do not fall from a great height onto the ore column, and do not develop a tendency for the charge to pack. Light loads of charge and low drop make a loose ore column and good smelting conditions. Stoking is another essential. The hand-operated furnace can be more successfully stoked to prevent crusts from forming and causing the charge to keep moving down and not be allowed to become dead in the furnace. The accumulation of dead charge in a furnace will at once cut down production and recoveries. As the metal bearing materials incipiently fuse and crust the furnace, loss of metal results, and all calculations are thrown out. Heavy wall crusts affect linings, by the more rapid deterioration of side walls. In all the above respects the hand-controlled furnace shows points of superiority in operation, recovery and production.

In furnaces having areas and volumes where hand labor for charging has to be eliminated, mechanical appliances must be used. The operation of some of these mechanical appliances has considerable to do with production and recoveries in the furnace. As the majority of such methods dump the charge from above and usually from 8 to 12 ft. heights and require rather large unit charges, a decidedly different set of conditions exists from that of charging small mixed charges by the shovel from a low fall. The large charge (500-1000 lb.) falls with considerable impact. The heavier material of the charge, falling with greater impact and settling first, upsets the proper feeding of the materials. This condition usually upsets the careful mixing which may previously have been accomplished. Also ore or limerock may fall around the electrode, when the opposite may be desired, and carbonaceous material falls next to the walls. By the carbon material falling next to the walls the temperature of the walls is considerably increased. This also results in areas in the center of the furnace being impoverished in reducing material. Also one part of the furnace may be running faster than another part and it may be necessary to place charge where most needed. This necessitates some rabbling and distribution of the material over the furnace top. With an 18 by 10-ft. furnace top area, this is inefficient at best. In rabbling, a workman usually draws or pushes more of the light material than heavy material, consequently uniformity throughout cannot be obtained. These conditions are prime effectives on production and recovery in an electric smelting furnace. These conditions also eliminate some of the smooth operations, such as occur on furnaces of lesser dimensions, volume and capacity. They will often account for otherwise unexplained factors.

COMPARISON OF METHODS OF CHARGING

It might be of interest to mention two methods of charging used on 20-ton alloy furnaces (20 tons of alloy per day). One method was by straight drop, and the other by a movable spout.

In the straight drop method, stacks were built between electrodes, and the charge dropped directly from above. The drop was about 11 ft. It was necessary to drop at least 500 lb. of mixed charge at one time. The

charge descended on the top of the ore column with heavy impact and packed the material densely around two adjacent electrodes, as the stacks were between. Then by rabbling usually the light charcoal was pushed or pulled away, and only ore and limerock were left around the electrodes. This condition, it was seen, soon upset furnace conditions and a change was necessary. The charges were then dropped, charcoal or coke first, and then ore and limerock. This rectified matters to a certain extent, but it required more labor on the feed floor, and caused considerable loss of charcoal, by dusting, and disintegration of lump charcoal when the ore fell upon it. The whole method of charging was then changed, having proved unsatisfactory.

A movable hopper over the furnace running on a track had an outlet into a long spout, which, being on a swinging joint, moved forward and backward. When a charge was dumped from the scale car into the hopper the spout was moved forward and backward, thus distributing the charge from front to back of the furnace. From the lip of the spout the charge fell about 3 ft. to the top of the ore column. As the deflection plate in the hopper was set at about a 45 degree angle, the velocity of the charge was checked from a straight-down fall, and as a result the charge fell with considerable less impact from the lip of the spout. In this way charcoal or coke could be fed separately, properly distributed, and ore following could be also be distributed. A minimum of rabbling was necessary and operations soon showed the merits of the change. The results were uniform smelting, absence of heavy crusts in the furnace, less labor necessary on the working floor, cooler top, better cooling of side walls, less dust in charging, less disintegration of charcoal.

The continual addition of 200 to 400-lb. charges is to be preferred to 700 to 1000-lb. charges dumped at long intervals of time. In this instance again, dimensional features and methods of meeting increased capacities control recoveries and production of metal. Also, the 16-ton furnace may be made equally efficient as and more efficient than the 5-ton furnace, by proper mechanical appliances.

While the method of charging a furnace is largely dependent on the quantity of charge required per unit of time, the capacity of the furnace usually decides the method to be used. With the dimensional features of the furnace already decided upon, the method of proper charging should be given careful consideration.

RELATIVE METAL RECOVERIES FROM DIFFERENT ORES

I also wish to refer here on the relative recoveries of metal from smelting carbonate ores, compared with smelting the oxide and silicate ores of manganese. Carbonate ores carrying not over 8 per cent silica should give lower losses from slag loss than silicate ores. As the manganese oxides are not chemically combined with silica to such large percentages in the carbonate ores, less slag losses would occur, the reason for this being freedom from rhodonite in the rhodochrosite ores.

In the silicate ores (rhodonite) the lime replaces some manganese oxide, forming lime silicates. But as lime replaces some manganous oxide, all replaced manganous oxide is not reduced by carbon to manganese. A large per cent of the manganous oxide passes again into solution with the silicates of lime and escapes reduction, forming double silicates of lime and manganese. Therefore on rhodonite ores and oxide ores carrying rhodonite, it is doubtful if slag content of manganous

oxide as low as 6 per cent and 8 per cent can be produced. The manganese dioxide, on which available oxygen is calculated, is also the base for available manganese. The following table gives analyses of some of the rhodonite ores smelted, the recoveries of alloy and analyses, with slag analyses, taken from operations on the 1800-kv. furnace referred to as the second furnace in this article:

ORE ANALYSES. RHODONITE AND OXIDE ORES

Mn	MnO	MnO ₂	SiO ₂	Fe ₂ O ₃
41.8	11.5	52.0	24.3	2.20
47.6	16.0	55.0	23.3	2.30
44.1	18.4	47.3	21.9	1.20
46.9	16.1	54.6	15.0	2.10
45.8	14.4	54.8	16.0	1.60
45.9	11.9	58.0	16.4	2.10

Manganese recoveries 72 per cent to 80 per cent

ALLOY ANALYSES

Mn	Fe	Si	S	P	C
81.9	9.50	0.95	0.034	0.044	7.05
82.5	10.50	1.60	0.020	0.085	4.95
81.4	11.55	1.35	0.005	0.090	5.55
81.3	11.50	1.41	0.004	0.102	5.55
82.0	11.20	1.56	0.002	0.075	4.95
81.7	11.80	0.50	0.003	0.090	5.75

SLAG ANALYSES

MnO	CaO	SiO ₂
14.6	41.7	36.8
17.9	42.2	34.7
16.7	42.3	34.7
16.3	41.3	36.0
14.4	42.0	40.2
11.18	44.8	37.2
18.8	34.5	37.2
17.5	39.7	36.6
16.2	37.6	35.7

The manganous oxide content of slags in these operations may have been decreased by increased carbon content on the charge. But as charcoal and coke were the items of greatest expense, it was necessary to conserve these materials. Also running on heavy lime burdens caused carbide accretions and electrode losses by carbon going into solution. As the manganese carbides form a soft disintegrating alloy, it was desired not to go over 6.5 per cent carbon in the alloy.

PROPERLY DESIGNED LARGE FURNACES ARE EFFICIENT

From the foregoing accounts it might be inferred that "large" size furnaces are considered wasteful and inefficient. But the "large" furnace properly designed in each component part can be made equally as efficient as a unit one-half or one-fourth the volume or capacity. By increasing the power input to double or triple is not alone sufficient. Decreasing the area of crucible to electrode area may not bring desired conditions. By a careful study of the relations which essential components bear to each other, the efficient operating unit can be constructed regardless of size of transformers, output and volume, etc. On equally rich burdens and nature and size of reducing agent and ore charge, electrical conditions may be brought to a condition of greatest heat development in the furnace. As the nature of the material in the furnace and the magnitude of its heating paths are the principal factors in producing heat, to bring about the chemical reactions these factors must be properly considered and utilized, so that large units may be built with high efficiency of power input and metal recovery.

In any smelting apparatus the rate of applying the heat is the essential problem. The chemical combinations involved produce both axothermic and endothermic reactions. Gases issuing from the furnace carry away heat units in their sensible heat. Radiation accounts for another decrease of heat in the furnace. By tapping slag and alloy, heat is again drawn from the furnace.

In the electric furnace, heat is supplied by the electrical resistance of the charge, and by multiple arcs of contact, at the electrode ends. The furnace must be in proper condition to quickly build up at all times its load for heat generation. The furnace crucible should be so proportioned that after tapping, large volumes of cold charge do not come down and cut off the load for long periods, by cooling the crucible and its contents.

The greater the rate of power input to the furnace the more easily can the operations be controlled. Power input is heat input. Rate of heat input means rate of metal output. Kilowatt-hour consumption is directly balanced against calories and metal output. But only by proper design can power input be properly and efficiently utilized for alloy or metal production and recoveries.

Milwaukee, Wis.

An Apparatus for Determining the Thermal Conductivity of Metals

BY GORDON B. WILKES

Assistant Professor of Industrial Physics, Massachusetts Institute of Technology

THE precise determination of the thermal conductivity of metals by a simple laboratory testing device is becoming of more and more importance in numerous technical and scientific lines. The enormous development of the gas engine in the last few years has brought forward the problem of cooling the cylinder and piston, and the thermal conductivity of the metals composing these parts plays an important part in the efficiency of any cooling system. All of the various types of heat interchangers are dependent primarily on the high thermal conductivity of their walls, which are usually composed of some sort of metal. The conductivity of the pure metals has been known with some precision for a long time, but that of the alloys is still unknown except in a few instances, and the thermal conductivity of an alloy cannot as yet be predicted from its constituents.

At the suggestion of Prof. Zay Jeffries, director of research, Aluminum Castings Co., the author designed and built the apparatus which is here described, for determining the coefficient of thermal conductivity of metals, especially aluminum alloys.

The apparatus was designed for use in a commercial laboratory and consequently was made as simple as possible, consistent with the results desired. It was required that the specimens be of such shape that they could be easily cast and prepared for testing with a minimum amount of machine work. The temperature range to be covered by the tests was from 20 to 600 deg. C., and the precision required was 2 per cent.

The familiar guard-ring method used so much for determining the thermal conductivity of heat insulators was used as the basis of the design, modified, of course, to meet the conditions of the problem. The tester consisted, essentially, (1) of a heater, (2) a guard-ring, not necessarily of the same material as the specimen, (3) two continuous flow calorimeters, and (4) three thermocouples used in measuring the temperature of different parts of the specimen.

Referring to the sketch of the apparatus, we have the heater 1, consisting of a coil of suitable resistance wire wound on a brass core, and insulated from it by thin sheets of mica. A suitable rheostat is connected

in series with this heater, in order that the temperature may be regulated at will, and an ammeter placed in the line is a great convenience, but not a necessity. This core is screwed into a hollow brass cylinder *B*, as shown in the sketch.

The specimen *C* is a rod, approximately 14 in. long and $\frac{3}{8}$ in. in diameter, the lower end of which is threaded into the brass cylinder *B* with a standard $\frac{3}{8}$ -in. thread, while the last 2 in. of the upper end is turned down to $\frac{1}{2}$ in. in diameter and cut with a fine thread, approximately 24 threads to the inch. The latter end has also a slot cut across the top, so that a screwdriver may be used for removing the specimen at the end of a test. The calorimeter *D*, which is screwed on this end of the specimen, is formed out of a solid cylinder of brass, drilled and tapped $\frac{1}{2}$ in. diameter, 24 threads to the inch, on top of which a $\frac{3}{16}$ -in. square thread is cut, forming the water passage around the specimen. The two ends of this square thread are connected to the two thermometer wells *E*, in which are inserted thermometers used in measuring the temperature of the inlet and outlet water.

The guard-ring *F* consists of a brass tube, 2 $\frac{1}{2}$ -in. outside diameter and $\frac{1}{2}$ -in. wall, which is screwed onto the brass cylinder *B*. The other end of the guard-ring has a square thread cut on the outside for a length of 2 in., over which a thin brass sheet is soldered, forming the guard-ring calorimeter. One end of this square thread is connected directly to the inlet water supply, while the other end first passes through a thermometer well, and thence to the waste pipe.

The temperature of the specimen is measured at three points along the rod, by means of small thermocouples inserted through holes drilled in the guard-ring and the specimen. The holes in the specimen should not have a diameter in excess of $\frac{1}{16}$ in., and are spaced 4 in. apart in such a manner that the center hole is equidistant from the calorimeter and the cylinder *B*. The space between the specimen and the guard-ring is filled with a thermal insulator (Fire-felt), in order to prevent convection currents from carrying heat to the calorimeters directly; in like manner the two calorimeters are insulated from each other, so as to eliminate any chance of transfer of heat between them. The entire apparatus is insulated on the outside with about 2 in. of good insulation to prevent any unnecessary heat loss and to secure constant temperature conditions.

The temperatures of the specimen and the guard-ring must be essentially the same where they leave the brass block *B*, both being screwed to the block and in intimate thermal contact with it; also the temperatures at the point where they enter their respective calorimeters must be the same, both being in contact with water at approximately the same temperature. If the specimen and the guard-ring are at the same temperature at their ends, and there is no appreciable heat flow outward in comparison with the flow of heat along the metal, any two points on the specimen and guard-ring, at the same distance from the heater, will be at

approximately the same temperature, and consequently there will be no transfer of heat between the specimen and guard-ring. In order to check this statement experimentally, thermocouples were placed on the guard-ring at points corresponding to the thermocouples in the specimen, and the temperatures at any two corresponding points were found to be the same.

If an electric current is allowed to flow through the heating wires, the temperature of the block *B* will be raised, and if a constant stream of water is maintained through the calorimeters, a uniform low temperature will be obtained at the upper end of the specimen and the guard-ring. The temperature of the block *B* will eventually become constant, provided the heating current is kept constant, and we shall have a uniform flow of heat along the specimen and the guard-ring toward the calorimeters. Any quantity of heat that enters the specimen from the block *B* will flow along the specimen without any gain or loss of heat until it reaches the calorimeter, because there is no tendency for heat to flow unless there is a difference in temperature. All of the heat that enters the calorimeter *E* flows from the specimen, because the calorimeter is very nearly at the same temperature as the surrounding air and the guard-ring calorimeter, and in addition is insulated from these.

When thermal equilibrium has been established, which takes about 2 hr., the coefficient of thermal conductivity may be calculated if the following data are known:

- A = Cross-sectional area of the specimen in sq. cm.
- D = Distance between any two thermocouples in cm.
- T_1 = Temperature of the hotter thermocouple in deg. C.
- T_2 = Temperature of the colder thermocouple in deg. C.
- T_3 = Temperature of the inlet water to "D" in deg. C.
- T_4 = Temperature of the outlet water from "D" in deg. C.
- W = Weight of water in grams, passing through the calorimeter during one second.

The coefficient of thermal conductivity, *K*, expressed in gram calories per second, per sq. cm., per cm. thickness, per 1 deg. C. temperature difference, may be calculated by the following expression:

$$K = \frac{W (T_4 - T_3) D}{(T_1 - T_2) A}$$

The data taken from a sample of commercially pure aluminum rod may be of help in showing how the values run for an actual observation.

$T_1 = 485$ deg. C.	$A = 2.86$ sq. cm.
$T_2 = 120$ deg. C.	$D = 20.3$ cm.
$T_3 = 16.13$ deg. C.	$W = 3.11$ g. of water per second.
$T_4 = 23.40$ deg. C.	

$$K = \frac{3.11 (23.40 - 16.13) 20.3}{(485 - 120) 2.86} = 0.440$$

In order to express *K* in B.t.u. per 24 hr., per sq. ft., per in. thickness, per 1 deg. F. temperature difference, the above value must be multiplied by 69,800.

In regard to the precision of the results, it will be seen readily that any of the factors used in the equation can be determined with much more than the required precision, consequently only the constant errors due to the design of the apparatus will affect the result so as to make the value of *K* in error more than 2 per cent.

The question of direct conduction to the calorimeter *D* by the insulation between the specimen and the guard-ring is negligible because the relative conductivity of the insulation and the specimen is about 1 to 2000, and their respective areas are approximately 7 to 1. The total amount of heat conducted by the insulation is only 7/2000 of the heat conducted by the specimen, and of course no large part of this heat would go into the calorimeter *D*. The question of a transfer of

SKETCH OF THE APPARATUS

heat between the specimen and the guard-ring depends upon the nature of the specimen and the guard-ring. If they are both of the same material, there will be no transfer of heat, because there will be no difference of temperature between the adjacent parts of the two. If they are not of the same material, their similarity of temperature and the transfer of heat between them will depend on possible differences in the temperature coefficients of their thermal conductivity, i.e., their change of thermal conductivity with temperature change, and is independent of their relative conductivities. Even at the worst, this loss is certainly small. The average area of the insulation, transmitting heat between the specimen and the guard-ring, is approximately 110 sq.cm., and assuming the relative conductivities stated above, the loss of heat to the guard-ring, with the specimen averaging 20 deg. C. higher temperature, will be only 1 per cent of the heat transmitted by the specimen. The temperature coefficients would necessarily have to be very different to produce an average temperature difference of 20 deg. C.

On account of the small temperature difference between the two calorimeters, which are also insulated from each other, there will be a negligible transfer of heat between them. If the thermometer wells are designed like those in the sketch, it has been clearly shown by a large number of tests that the thermometers will truly record the temperature difference between the entering and exit water and there will be no chance of any error from this source greater than $\frac{1}{2}$ or 1 per cent. I believe that all of the larger sources of error have been taken into account and that they cannot affect the result by amounts as large as 2 per cent.

In conclusion, it might be of interest to state that an apparatus of this sort has been in use for over six months in a commercial laboratory and has given satisfactory service. I also wish to express my thanks to Prof. C. L. Norton of the Massachusetts Institute of Technology for his help in the design and construction of this apparatus.

Cambridge, Mass.

Mine Output of the Central States, 1918

The 1918 production of non-ferrous metals from the mines of the Central States was 73,643,398 short tons less than for 1917, in value \$30,861,000. The decrease, principally due to the curtailment of production of the Michigan copper mines, was for copper 28,703,337 lb. and for silver 192,746 oz.

The output of Missouri zinc decreased 76,926 short tons, while the Oklahoma production increased 75,566, the two States changing places as the largest producer.

Producer Gas Costs

The following table of producer gas costs published by the Steere Engineering Co., Detroit, includes fuel, power, repairs and maintenance, labor and supervision, interest and depreciation; in fact, every item of cost except the interest and taxes on the land occupied.

Producer Gas Costs per 1000 Cu.Ft. for Coal Costs Given		Costs at Which Other Fuels Must Be Bought to Obtain the Same Number of Btu. as When Burning Producer Gas With Coal at the Price Given									
Cost of One Ton of Coal at Plant	Hot Raw Producer Gas at Offtake	Clean Cold Producer Gas	Hot Raw Gas	Clean Cold Gas	Hot Raw Gas	Clean Cold Gas	Hot Raw Gas	Clean Cold Gas	Hot Raw Gas	Clean Cold Gas	Hot Raw Gas
\$2.00	3.13c.	4.15c.	23.76	31.5c.	2.91c.	3.86c.	12.6c.	16.72c.	6.45c.	8.59c.	
2.50	3.55c.	4.57c.	26.9	34.67	3.3	4.25	14.3	18.40	7.14	9.45	
3.00	3.96c.	4.98c.	30.1	37.84	3.69	4.64	16.6	20.09	8.20	10.32	
3.50	4.38c.	5.40c.	33.3	41.01	4.08	5.03	17.65	21.77	9.07	11.18	
4.00	4.79c.	5.82c.	36.5	44.18	4.46	5.42	19.3	23.45	9.92	12.05	
4.50	5.21c.	6.24	39.5	47.35	4.85	5.81	21.0	25.13	10.78	12.91	
5.00	5.63c.	6.66	42.7	50.52	5.24	6.20	22.7	26.82	11.65	13.78	
5.50	6.05c.	7.08	45.9	53.69	5.63	6.59	24.35	28.50	12.5	14.64	
6.00	6.46c.	7.49	49.1	56.85	6.01	6.97	26.0	30.18	13.36	15.50	

HEATING VALUES USED

Producer gas.....	145 B.t.u. per cu.ft.
Natural gas.....	100 B.t.u. per cu.ft.
Fuel oil.....	135,000 B.t.u. per gallon
Coal gas or carburetted water gas.....	585 B.t.u. per cu.ft.
Blue gas.....	300 B.t.u. per cu.ft.

These costs are based on the plant operating with a 100 per cent load factor, that is, operating at rated capacity 24 hours per day, 365 days per year. Comparatively few plants have a 100 per cent load factor, and therefore it is necessary to take this very important point into consideration when estimating the cost of gas.

The cost of producer gas, with a reasonable degree of accuracy, may be estimated for any load factor by applying the formula:

$$C = T + \left[\left(\frac{R}{A} - \frac{400}{B} \right) \cdot 2.38 \right]$$

Where

C = Cost of producer gas per thousand cu.ft. under conditions specified

A = Number of feet of gas used per day

B = Days per week plant is in operation

T = Cost figures shown in table at 100 per cent load factor

R = Rated hourly capacity of plant in cubic feet

It also must be kept in mind that furnace efficiencies have a very great bearing on the cost of the finished product. Without regeneration or recuperation producer gas cannot be used as efficiently as the more concentrated fuels. The expense of the distribution system and the furnaces also have an important bearing on the total cost of doing the work.

MINI. OUTPUT OF THE CENTRAL STATES, 1918 (a)
(1917 Output Shown for Comparison)

State	Ore Treated (Short Tons)		Silver (Fine Oz.)		Copper (Lb.)		Lead (Short Tons)		Zinc (Short Tons)		Total Value

(a) The average market prices used by the U. S. Geological Survey in figuring values of production of metals for the calendar year 1918 are: Silver (average price as given by Bureau of the Mint), \$1 per fine oz.; copper (sales price all marketable grades), \$0.247 per lb.; lead (sales price all grades), \$0.071 per lb.; zinc (spelter) (sales price, all grades), \$0.091 per lb.

(b) Includes only ore from Northern Illinois.

(c) Tonnage not available.

The Flash and Burning Points of Gasoline-Kerosene Mixtures*

Effect of Gasoline Content on the Flash and Burning Points of Kerosene — Foster Closed Cup and Cleveland Type Open Cup Methods Compared — Flash and Burning Points of Kerosene Mixed With "Low-Test" Gasoline, "High-Test" Gasoline and "Petroleum Ether"

By JAMES T. ROBSON AND JAMES R. WITHROW

THE results indicated by the investigations covered in this paper and by the literature on the subject which is reviewed herein are:

The profound effect upon the flash and burning point of kerosene and therefore the fire and explosion hazard of the smallest percentages of gasoline or similar volatile petroleum fractions added to the kerosene.

Gasoline cannot safely be permitted in kerosene.

The early records of the influence of light petroleum distillates upon burning oils were based upon fractions radically different in properties from similarly named products of modern refining.

The main original need for State flash point laws has ceased. Nevertheless, public safety still requires their enforcement.

The Foster closed cup flash determination permits the presence of much lighter petroleum distillates than the Cleveland open cup method.

The gasoline and other light petroleum fractions are found to be miscible instantaneously with kerosene if intimately mixed. It is concluded that stratification in large tanks is merely due to insufficient mixing or lack of time for diffusion.

While ordinary kerosene of commerce extinguishes a burning match, the addition of gasoline to the extent of 1 per cent may give a flash; 3 to 5 per cent gives violent flashing, and 7½ per cent inflames at once. Any of these would have given explosions if confined.

The relation is established between flash and burning point and percentage of volatile petroleum fractions admixed with kerosene. Working conditions are given minutely, to establish the comparative dependability of the final values for future cases of comparison. Distillation and gravity characteristics of the fractions used are recorded.

Because of our inability to obtain material assistance from the literature on the influence of the addition of gasoline to kerosene with respect to the explosion hazard after the kerosene was marketed, it seemed desirable to publish portions of the work made necessary by this scanty literature.

FATAL RESULTS FROM GASOLINE-CONTAMINATED KEROSENE

One or several deaths appear to have resulted from explosions in the use of kerosene admitted to have been marketed in Ohio by an oil refiner. It is also admitted that an employee of the refiner inadvertently pumped gasoline into a kerosene storage tank and also that kerosene was subsequently sold from this tank batch. It was claimed by the plaintiffs that the kerosene causing fatal explosions could be directly traced to this contaminated kerosene storage. It is claimed by employees of the refiner that a gallon sample was drawn off of the contaminated kerosene tank and its flashing properties tested and found "safe."

It would probably have to be admitted that a draw-off of one gallon would not clear the uncontaminated kerosene from the draw-off line, and as a result the

"safe" flash test would not reveal the true character of the tank contents. In this same connection also it was claimed by the plaintiff that stratification probably existed in the tank anyway and therefore a sample withdrawn from the bottom of the tank would inevitably test "safe" in flash point. It was also claimed that dispensing from said tank would soon reach a highly dangerous zone because richer in gasoline.

No exact evidence was available as to the amount of kerosene originally in the tank or the amount of gasoline pumped into it or the amount of the mixture resulting. It would probably have to be admitted, however, that there was more than 2 per cent gasoline as a minimum admixed with the kerosene or any lot sold therefrom if admixture were complete. No actual sample of the mixture appears to have been preserved by either side. The samples causing the explosions were destroyed thereby.

In 1861 Allen (*Smithsonian Reports*, 1861, p. 330) reported on the "Explosibility of Coal Oil," an investigation instigated by the Rhode Island Mutual Fire Insurance Co. to study various "coal oils." Both petroleum and coal-tar products were included under "coal oil." That gasoline was then a drug on the market was pointed out, as was the artificial production of kerosene with a kerosene gravity by judicious mixtures of higher and lower fractions than the kerosene fraction proper.

Allen made flash point determinations in open cups floating in water at various temperatures. This seems to us a cumbersome manipulation as compared with our simple direct heated or water-bath heated devices. He did not know the amount of "adulteration," however.

K. V. Weise in Wagner's "Chemische Technologie," 1871, p. 865, with the open cup method found:

	Sp.Gr.	Flash Point, Deg.	Burning Point, Deg.
Petroleum.....	0.805	30	43
Petroleum + 1 per cent naphtha.....	0.710	25	40
Petroleum + 1 per cent naphtha.....	0.710	22	32
Petroleum + 3 per cent naphtha.....	0.710	20	29

This work is by far the most complete along this line in the literature. The oils used, however, are quite different from those with which we are concerned. The closest to our conditions are these:

	Flash Point, Deg.	Burning Point, Deg.
Petroleum, 0.806.....	55	70
Petroleum + 2 per cent naphtha.....	45	60
Petroleum + 4 per cent naphtha.....	24	55
Petroleum + 10 per cent naphtha.....	20	32

There was no closed cup work. The author states that for the determination of the naphtha content, neither the flash point method nor fractional distillation is satisfactory.

In 1887 Crew ("Treatise on Petroleum," 1887, Philadelphia, Henry C. Baird & Co., p. 395) pointed out

*Read at the meeting of the American Institute of Chemical Engineers, Cambridge, Mass., June 20, 1919.

adulteration of kerosene with dangerous low-boiling fractions and presented a simple "saucer" test to show whether or not a given oil was dangerous for use in lamps.

Crew quotes experiments of Dr. C. B. White of New Orleans resulting as follows:

	Flash Point, Deg. F.	Burning Point, Deg. F.
Oil alone	118	135
Oil with 1 per cent benzene—65 deg. B.	112	129
Oil with 5 per cent benzene—65 deg. B.	103	123
Oil with 5 per cent benzene—65 deg. B.	96	116
Oil with 10 per cent benzene—65 deg. B.	81	102
Oil with 1 per cent benzene—72 deg. B.	107	131
Oil with 5 per cent benzene—72 deg. B.	70	105

Allen's "Commercial Organic Analysis," 4th ed., Blakiston, Philadelphia, 1914, p. 120, states that Dr.

FIG. 1. OPEN CUP FLASH POINTS—EARLY WORKERS

B. W. White, using the "open test," with oil which originally flashes at 113 deg. F. found that

- 1 per cent naphtha reduced flash point to 103 deg. F.
- 2 per cent naphtha reduced flash point to 92 deg. F.
- 5 per cent naphtha reduced flash point to 83 deg. F.
- 10 per cent naphtha reduced flash point to 59 deg. F.
- 20 per cent naphtha reduced flash point to 40 deg. F.

No further information is given. It is not evident whether this is the same Dr. White referred to by Crew.

These results correspond only approximately with ours. They are upon the older type of low-flash kerosene and with uncertain procedure. They are interesting, however, as tending to show the influence of definite admixture of an oil of known flash point. No modern case has been found by us where there is a clear correlation between definite admixture of characterized products and the flash and burning tests with prescription of conditions of test.

Steingraber (*Oesterr. Chem. Zeit.*, 1900, pp. 589-99; *J. Soc. Chem. Ind.*, 1901, p. 352) tried to determine how far the properties of "illuminating" fractions of oil were affected by benzene mixtures. He used 21 deg. C. flash oil as standard and added various amounts of benzene and higher fractions. His results showed that only benzenes boiling below 100 deg. C. have strong influence on flash. Additions of higher boiling benzenes

have little effect; 21 deg. C. (or 70 deg. F.) is too low as a flash oil to be taken as a standard to determine effect of benzene on flash. With 110 to 120 deg. F. flash oils as standards, effect of higher boiling benzenes are somewhat different than found by Steingraber.

H. C. Sherman, T. T. Gray and H. A. Hammerschlag (*J. Ind. Eng. Chem.*, vol. 1, 1909, p. 13) compared the calculated and determined viscosities and flashing and burning points of oil mixtures. This work shows that the calculated flash point is not the same as the actual. The work was not on kerosene, however.

J. A. Harker and W. F. Higgins in "The Methods and Apparatus Used in Petroleum Testing" (*Nat. Phys. Lab., Collected Researches*, vol. 8, 1912, p. 38) give a method for calculating flash points of different mixtures of oils. No method is given of identifying their oils.

Intervals (10 per cent) of mixture used are so large that it is not justifiable to determine flash point for any intervening mixture, say 92 or 97 per cent.

Harker's work intends to give a method of determining the flash point when the composition is known but omits identification of his oil.

Our work will give approximately the composition of the mixture from a determination of the flash point

FIG. 2. BURNING POINTS—EARLY WORKERS

and interpreting on the basis of the distillation curves which identify our oils.

Curves representing the values recorded by these earlier workers appear in Figs. 1 and 2.

FACTORS INFLUENCING FIRE HAZARDS OF GASOLINE AND KEROSENE

Strictly speaking, the flash point by itself does not determine the fire hazard of any substance. The factors which also influence fire hazard are:

- (a) Volatility.
- (b) Boiling point.
- (c) Vapor pressure.
- (d) Vapor density.

- (e) Diffusibility and tendency of vapors to travel.
- (f) Explosive limits in air.
- (g) Tendency to chemical change.
- (h) Quantity of heat liberated per unit of volume.
- (i) Temperature of flame.
- (j) Corrosive action.
- (k) Behavior toward water before and after ignition.
- (l) Tendency of substance to leak.
- (m) Prolonged heating effect.

Kerosene in a tropical climate gives lower "flash" than the same oil in a temperate climate. The trouble is due primarily to accumulation of vapors caused by continued high temperature and secondarily in discharging or moving oil by vapors disengaged on pouring and shaking.

It is well known that cold kerosene of good legal quality will not take fire when light is applied, nor will the supernatant vapor inflame. The "burning test," fire test, i.e., temperature at which oil permanently inflames, is sometimes taken as a test of burning or firing value, but is not strictly reliable since oils spilled in a thin flow will ignite instantly on approach of a flame, even when the burning point is considerably higher than the flash point. It is also well known that with refined burning oil no inflammable or explosive mixture could be formed, even in the absence of ventilation, up to 70 deg. F. At temperatures much above 80 deg. F. and with no ventilation, such an atmosphere could be produced with most oil.

EARLY FLASH POINT LAWS AND PRESENT REVERSED STATUS OF GASOLINE AND KEROSENE PRODUCTION

It would have to be admitted that the presence of lighter or gasoline fractions in kerosene has long ceased to be profitable to the refiner. Hence as an evil it has needed little attention in recent times.

If commercial gasoline of any gravity is accidentally pumped into or by faulty valving or otherwise gets into a kerosene fraction storage, its detection is quite simple by the flash test. Simple considerations indicate, however, that this can be no quantitative indication of the amount of such contamination except the "flash point" determination be calibrated with reference to this particular kind of occurrence. Individual oil companies or chemists doubtless have felt the need for such a correlation and perhaps have made it. Few of these results have gotten into the literature. From year to year we have had cases arise which raised the question: "How much gasoline does this particular contamination represent?" Recently the question arose again under the circumstances already mentioned, which made a partial answer to the general question necessary, and the results obtained with our set of conditions are here recorded.

In the earlier period of petroleum refining, kerosene or "burning oil" was the valuable light product or early distillate. At that time it was a temptation to producers to put into kerosene all the traffic would stand of lower boiling (gasoline) fractions, together with the maximum of higher boiling fractions next above the burning oil, to balance the lighter gravity of the gasoline fraction. This virtually amounted to a physical synthesis of kerosene by mixing with each other the next lower and higher fractions. This was a perfectly justifiable procedure, if a safe one, to meet commercial demands in the days that developed "cracking" for burning oil formation. "Gravity," however, was not the sole consideration. There was a safety limit which was important because the consumers in the homes of

the land might be made the victims of unnecessary fire hazard, through refiners' carelessness or unscrupulousness in this connection. Many tragedies resulted and legislation put a curb to syntheses of this kind by setting legal limits in a modified practical safety test in the flash point laws.

Of the law requirements (Gill's "Oil Analysis," 3rd ed., J. B. Lippincott, Philadelphia, p. 131; Stillman's "Engineering Chemistry," Chemical Publishing Co., Easton, Pa., 1916, p. 450) in 31 States, 19 fix a minimum flash point of 100 to 125 deg. F. and 12 States make a minimum "burning point" instead of flash point requirement. The burning point runs from 100 to 150 deg. F. in the States making the requirements. Four States set both a minimum flash and burning test and 16 no burning point test at all. These State laws specified in all except 8 cases the form of test, whether in "open" or "closed" apparatus. In only four cases was "open" testing permitted. In all other cases a closed tester was prescribed, thus closely simulating lamp or confined conditions, and the specific instrument was named such as the Tagliabue or Foster. From the results herein reported it will be seen that the closed cup of the Foster type may permit the presence of much more gasoline in a burning oil than does the open cup test for the same flash point.

GASOLINE AT THAT TIME A DRUG ON THE MARKET

In that early period of the petroleum refining industry, gasoline was a drug on the market. All the art of sales was directed to the creation of an outlet. The public had to be protected, therefore, against unscrupulous addition of gasoline to kerosene to increase production volume of the latter. Now the situation is reversed. The advent of the hydrocarbon or internal combustion engine about 1898 has created ever increasing demands for the gasoline fraction, so that the kerosene demand by comparison stands still. Now, as a result, the refiner puts everything into gasoline that the traffic will stand. This is as it should be, if understood. Consequently, the cheaper kerosene fraction is stripped as lean as possible of volatiles to raise the volume of the gasoline fraction. This puts so much of the front end of kerosene into gasoline that, of course, the gasoline is made heavier in gravity as is the kerosene. This greatly raises the flash and burning point of the kerosene, because the more volatile portion was cut off to add to gasoline. This is so effectively done in wide awake refineries that the State flash point laws are almost a dead letter. They, nevertheless, are necessary, because there are still a few poorly equipped or carelessly operated refineries. Occasionally errors or accidental contamination of kerosene storage will occur and the plant manager refuses to re-strip the mixture to save expense and instead works it off on the trade. We seem to meet occasionally just this situation in Ohio State oil inspection, and the protection to the public in these cases justifies the continuance of this State activity. In addition, there are the mistakes of delivery and petty storage-filling between wholesaler, retailer and eventual delivery to consumer. These, while not common, are much more common than refiners' mistakes, but are depressed in number by vigorous legal inspection and law enforcement, particularly in rural sections.

When the State Oil Inspector's office picks up offenders under the Ohio law it at times can trace a somewhat

connected series of infractions indicating a bad lot of kerosene and at times traceable to the refinery. In referring such matters to this laboratory the question is sometimes asked about the extent of gasoline contamination. It is not necessary to cite cases except to state that confirmation of the field inspector's test have at times been so good as to have the product pop off on lighting the paper in the Foster closed cup (the legal test instrument in Ohio). The taper is lighted customarily at 90 deg. F. and the Ohio minimum flash point for kerosene is 120 deg. F. Such a product is highly dangerous as a kerosene.

For this portion of the public welfare and safety, the State oil inspection laws are still an important factor. Careful, honest dealers and refiners have no quarrel with these laws.

THE FLASH AND BURNING POINT TESTS

There are some factors which must be clearly understood when dealing with flash point determination. The substances kerosene and gasoline themselves are not chemical compounds, but mixtures of hydrocarbons. "Kerosene" is a trade name. It is also called "coal oil" and "illuminating oil." Industrially it is understood to be a mixture of hydrocarbons "entirely" free from gasoline and naphtha on the one hand and from heavy hydrocarbons belonging to gas oil and lubricating oil on the other. This (kerosene) mixture is supposed to be only moderately soluble in alcohol but miscible in all proportions with ether, chloroform, benzene, petroleum spirit, volatile and fixed oils except castor oil.

Gasoline is a mixture of the lower series of hydrocarbons. It is lower in boiling point and lighter in gravity than kerosene. It includes all of them that are not "wild" or which will stay in a reasonably corked container and running as heavy in gravity as motor vehicles can start and navigate under. It usually includes all the old materials called variously petroleum spirit, petrol, benzine, etc. Formerly, that which distilled below 150 deg. C. was "spirit" or gasoline; 150 to 270 deg. C. was kerosene, and 270 deg. C. up was heavy oils. This was only conventional. Refineries ran largely on gravity. The consumer became acquainted with a specific gravity test. It was easy to perform and the refiner cut his fractions at various gravities in order to have his cuts average some other gravity required in the trade.

The flash point is the lowest temperature to which the oil need be heated under a fixed set of conditions to give off vapors in sufficient quantity when mixed with air to explode upon the approach of a flame.

The burning point or "fire test" is the lowest temperature at which oil will give off sufficient vapors to burn continuously when ignited.

The flash point and burning point tests are arbitrary. They are not measures of rigorous constants, yet they are capable of much refinement. They are accurate determinations of the practical effects of complex factors. For these reasons the values as determined are susceptible to influence from many sources, among which may be mentioned:

1. Barometric pressure.
2. Nature of bath as a source of heat.
3. Design of oil cup.
4. Features of thermometer.
5. Rate of heating.
6. Effect of prolonged heating or cooling.

7. Manipulation of test (manner flame is applied for flashing, etc.)

8. Room temperature and conditions.

9. Initial temperature of oil being tested.

10. Influence of water presence.

11. Personality of operator.

Even the determination of the flash point of a pure hydrocarbon (from the mixture whose vapor pressure effect is really the matter at issue) would be influenced by most of these factors.

The aim was a practical test, and experience has forced precautions and developed refinements. Burrell and Boyd (U. S. Bureau of Mines Tech. Paper 117) have pointed out the relation between vapor pressure and explosiveness of air gasoline mixtures as related to sewer atmosphere. No one appears to have correlated vapor pressures and explosion and ignition studies of vapor-air mixtures in connection with flash point determinations. The machines in use are accurate enough for short-cut results and are certainly practical in that they simulate burning lamp conditions.

CHARACTER OF THE MISCIBILITY OF GASOLINE-KEROSENE FRACTIONS

Among the questions raised in connection with the litigation referred to were (1) the nature or degree of miscibility of gasoline and kerosene fractions in each other, and (2) the influence upon the flashing properties of a kerosene in the event of miscibility proceeding at a practically instantaneous rate.

It is well known that petroleum fractions are miscible in one another. It cannot, therefore, be assumed that this has no limit in the case of any two restricted fractions in the absence of whole series of hydrocarbons of the original petroleum. Experiment upon various "gasolines" and a sample of kerosene, using every precaution to prevent mechanical mixing, practically always resulted, in the laboratory, in a product with the same flash and burning point as a thoroughly mixed sample. This appeared to be independent of the time of contact, position of admission to the kerosene, depth of kerosene layer (up to 1 ft.), portion of layer from which test sample was withdrawn, and the relative proportions used. This completely answers the ultimate degree of miscibility of the gasoline and kerosene fractions available for our experiments. The results also appear to answer the question of the nature of miscibility, i.e., it appears to be instantaneous. As these were laboratory experiments, they cannot be offered as conclusive, for they are subject to the criticism that an apparently instantaneous time factor in the laboratory may be quite a different matter in the plant where great volumes and depths of tank are factors modifying the situation. Also it is well known to refiners of light-boiling oils such as petroleum and coal-tar hydrocarbons that mixing or blending in tanks even as small as 10 x 12 ft. does not proceed automatically upon mere addition, but air agitation is necessary to insure completeness of mixing. We possess no exact knowledge on this subject and carried out no experiments in view of the trouble and expense attached thereto and because of the existence of definite experience that miscibility has a real time factor in large-scale operations. As an illustration, petroleum distillate tanks have been known to test 45 deg. B. at the bottom, 47 deg. at the middle and 49 deg. at the top. Again, pumping a light gravity oil into a 250-bbl. tank containing heavier oil, inlet at bottom, showed, when

240 bbl. were in the tank, 58 deg. B. at the bottom, 61 deg. at the middle and 68 deg. at the top; quantities used not known.

THE INFLAMMABILITY OF GASOLINE-KEROSENE MIXTURES

The following results indicate the effect upon the flash and burning behavior of kerosene used by admixtures of gasoline at ordinary temperature. These experiments were carried out in an ordinary granite ware cup, using 100 cc. of oil each time. In these experiments, "low-test" gasoline was used. The kerosene was measured in a 100 cc. graduate and the gasoline up through 3 per cent was measured in pipettes. From 5 per cent on, the gasoline was measured in the cylinder. With 100 per cent kerosene a lighted match when applied quickly or very slowly was extinguished. With 99 per cent kerosene and 1 per cent gasoline the match flashed when added but was extinguished when immersed in oil. With 3 per cent gasoline and 97 per cent kerosene, there was a flash more noticeable than with the 2 per cent mixture, but the match was also extinguished when immersed in the oil. With 5 per cent gasoline and 95 per cent kerosene the oil flashed violently, but did not burn. With 7½ per cent gaso-

FIG. 3. OPEN CUP OIL TESTER

line and 92½ per cent kerosene the oil flashed with a puff and readily burned when the lighted match touched it. With 12½ per cent gasoline and 87½ per cent kerosene the oil flashed with a loud puff and readily burned when the lighted match approached it.

FLASH AND BURNING POINTS OF KEROSENE-GASOLINE MIXTURES

Since so little is said in the literature about the effects of highly volatile petroleum fractions upon the flash and burning point constants of ordinary kerosene, we have determined the influence upon them in the case of a kerosene mixed with "low-test" gasoline, "high-test" gasoline and "petroleum ether." Both the open and closed cup methods were used for flash point determinations.

The open cup test depends not only upon the skill of the operator but also the condition of the atmosphere, and is affected by the slightest current of air. It is a reliable test, however, for such cases where an oil will be heated in open vessels to determine to what degree it can safely be heated without ignition by flame. With such a case the open test is an actual imitation of the real conditions and therefore fully warranted.

The flash point of kerosene should be high enough so that it will insure safety when the kerosene is burned in a lamp. Danger from a petroleum lamp can occur if the flame flashes back into the petroleum reservoir by accident or carelessness and ignites the vapors which had accumulated in the closed basin. (*Proc. Am. Soc. Testing Materials*, vol. 10, p. 464, 1910.)

The Foster cup method is the standard method for determining the flash point of kerosene prescribed by the law in Ohio, which states that kerosene shall not flash below 120 deg. F. by this method. (*Allen's "Commercial Organic Analysis,"* 3d ed., p. 127.)

METHOD OF USING OPEN CUP PROCEDURE

For determining the open cup flash and burning points an apparatus similar to the Cleveland open cup was used, with the addition of a casing to more efficiently prevent drafts of air. A sketch of this apparatus is shown in Fig. 3. It consisted of a 40 cc. nickel crucible A, whose upper surface measured about 4 cm. in diameter. This was placed inside a large 120 cc. nickel crucible B, which contained sand to a depth of about 2 cm. This sand bath was then supported in the flame guard C by means of the asbestos board D, which had a hole cut in its center to admit B as shown. The flame protector was supported on the tripod stand E. Heat was supplied by the bunsen burner F as shown. The whole apparatus was protected from air current by the casing of thin sheet copper G. A thermometer was held suspended in the oil by means of a burette clamp on a ring stand. An ordinary mouth blow pipe connected to the gas cock by rubber tubing was used as a tip for the flame to be passed over the oil.

After thoroughly shaking the oil sample, the small crucible was filled to within ½ cm. of the brim. This required 32 cc. The thermometer was then lowered by sliding the burette clamp on the ring stand. The thermometer was held at such a height by the clamp that when the clamp was lowered to the top of the copper shield the bulb was totally immersed in the center of the oil to the same depth each time. Heat was then applied by means of the bunsen burner, so that the temperature rose at the rate of 5 deg. C. per min. The test torch was then lighted and the flame made ½ cm. in length. As the flash point was approached, for every degree rise in temperature the flame was passed slowly over the cup horizontally about 1 cm. above the surface of the oil and near the thermometer.

After obtaining the flash point, the test flame was still passed over the oil in a similar manner until the oil permanently ignited. The thermometer was then quickly raised from the oil and the flame in the cup extinguished by excluding the air by means of a solid piece of asbestos board placed over the cup.

All open cup temperatures were read on a 400 deg. C. thermometer. The calibration of this thermometer was checked up by comparing its two fixed points 0 deg. and 100 deg. C. with a standard thermometer. To fix

the zero point, the thermometer was surrounded by melting ice and the reading compared with that of the standard thermometer under the same conditions.

The 100-deg. point was then determined by placing the bulb of the thermometer used in the neck of an Erlenmeyer flask containing boiling water so that it was entirely surrounded by steam and the reading on the thermometer was noted in comparison with that of the standard thermometer under like conditions. The barometer reading was also taken and corrections applied. The uniformity of the bore was checked up by detaching a thread of mercury and measuring its length throughout different portions of the stem between 0 deg. and 300 deg. Required corrections were applied throughout all of the work.

For each succeeding test the warm sand from the test preceding was emptied from the cup and fresh sand put in, so that all tests were made under exactly the same conditions. The cup was then cooled by immersion in cold water and thoroughly dried.

In testing mixtures where the flash point was below room temperature, the sand was omitted from the bath, and cracked ice, or ice plus calcium chloride, when necessary, was substituted. Cases where this was required are marked on the table by an asterisk (*).

METHOD OF USING CLOSED CUP PROCEDURE

A standard Foster cup apparatus was used. Its thermometer was checked against U. S. Bureau of Standards thermometer No. 4576. The method of procedure in determining the flash point by the Foster cup was as described in Stillman's "Engineering Chemistry," pp. 448-449. This was as follows: The thermometer with its mounting was removed from the oil cup. The oil cup containing the flashing taper was removed and the open water bath half filled with water. The flashing taper was then removed from the cup and, after thoroughly shaking the oil in its container, it was carefully poured into the cup at the place of the flashing taper wick holder until it just reached the gage mark at the thermometer hole. The cup was then tipped so that the oil flowed away from the gage, and was then gradually restored to the horizontal position. If the surface again adhered to the mark, it was all right; in case it did not, a little more oil was added. The flashing taper was then adjusted to give a flame $\frac{1}{2}$ in. in height. The oil cup was now set in the water bath, the flashing taper returned to its place, the conical thimble inverted around it and the thermometer returned to its place upon the cup, care being taken that the latter was pushed down upon the cup as far as possible. The lamp beneath was half filled with alcohol, lighted, and placed beneath the water bath. The wick was so adjusted that the temperature of the oil was raised at the rate of 2 deg. F. per min. When the thermometer read 90 deg. the flashing taper was lighted and closely observed. In tests where the flash point was 90 deg. or lower, the flashing taper was placed in the cup before applying heat from below. In several instances, as previously mentioned in the open cup method, the mixtures flashed below room temperature. In these cases cracked ice was placed in the water bath and the test repeated. These cases are shown by an asterisk (*) in the tables.

A rather peculiar phenomenon took place in the closed cup flash test. When the oil was previously cooled by ice, it flashed some 5 or 6 deg. higher than when not

previously cooled. Thus, in the case of the 7 $\frac{1}{2}$ per cent mixture of high-test gasoline and kerosene when ice was not used in the bath it flashed at 75 deg. F. (as soon as the pilot was lighted). However, when previously cooled by ice, the mixture had to be heated to 84 deg. F. before flashing, the pilot burning constantly. This may be due to the design of the cup. The flashing taper when in place forms a draft so that when lighted while the oil was below 75 deg. the volatile gases liberated would pass out through the opening and escape, whereas when no light was present the draft was not so great and consequently the concentration of highly volatile vapors in the cup would be greater, so that when a flame was admitted at 75 deg. the concentration of the gases was enough to extinguish it.

All flash points in both open and closed cup have been corrected for normal barometric pressure, 760 mm., by Table I (U. S. Bureau of Mines Technical Paper No. 49). In order to show to what extent the barometric pressure affects the flash point, the solid curves

FIG. 4. FLASH POINTS OF GASOLINE-KEROSENE MIXTURES—OPEN CUP METHOD

have been drawn which represent the flash points when corrected for barometric pressure and the dotted curves which do not include barometric pressure correction.

No corrections for pressure have been applied to the burning point results, as no correction table was available.

The kerosene before being used in these tests was filtered through filter paper to remove all traces of moisture fog.

DISCUSSION OF RESULTS

The tables and accompanying Figs. 4, 5 and 6 show the results obtained by these tests. Blank spaces in

the tables show that the tests were either unable to be carried out because of the low temperature required or the test was considered unsafe.

FLASH AND BURNING POINTS OF "LOW-TEST" GASOLINE AND KEROSENE

Gasoline by volume, per cent.....	0	1	2	5	7.5	10
Kerosene by volume, per cent.....	100	99	98	95	92.5	90
Open cup flash point, deg. F.:						
Without barometric correction.....	118.4	105.8	100.4	84.2	65.3*	35.6*
With barometric correction.....	120.0	107.4	102.0	85.8	67.0*	37.2*
Foster cup flash point, deg. F.:						
Without barometric correction.....	128.9	119.3	114.5	95.0	88.6*	
With barometric correction.....	130.5	120.9	116.1	96.6	90.2*	
Burning point, deg. F.....	134.6	125.6	122.0	112.1	99.5*	78.8*
Gasoline used: "Low-test."						
Specific gravity = 0.738 = 59.7 deg. B. at 15.5 deg. C.						
Kerosene used:						
Specific gravity = 0.815 = 41.8 deg. B. at 15.5 deg. C.

Kerosene used:				
Specific gravity = 0.815 = 41.8 deg. B. at 15.5 deg. C.				
* Shows that freezing mixture was used in bath.				

In the open cup method the flash points of the "high-test" gasoline-kerosene mixtures were naturally lower

FIG. 5. FLASH POINTS OF GASOLINE-KEROSENE MIXTURES—FOSTER CUP METHOD

than the corresponding mixtures of "low-test" gasoline, being a minimum of 2.1 deg. F. less at 1 per cent and 7.5 per cent gasoline and a maximum of 5.7 deg. F. less at 10 per cent gasoline. The fact that a minimum difference occurred at both 1 per cent and 7½ per cent shows that the open cup flash point of the "low" and "high" test gasoline-kerosene mixtures did not fall at the same rate with increase in percentage of gasoline.

In the case of the closed cup the flash points for mixtures above 2 per cent high and low test gasoline regu-

FIG. 6. BURNING POINTS OF GASOLINE-KEROSENE MIXTURES

larly fall at different rates, with increase in concentration of gasoline as shown by the curves falling away from one another. This shows that the open cup method does not bear a constant relation to the closed cup method, or, graphically speaking, their curves are not the same shape.

The flash point of the petroleum ether-kerosene mixtures decreased regularly with increase in concentration of petroleum ether so that in the case of the open cup method the curve was almost a straight line, and in the case of the closed cup method it was a straight line.

The lowering in the flash point of kerosene by adding petroleum ether was remarkable. In the open cup method 2.9 per cent petroleum ether lowered the flash point of the kerosene about 88.5 deg. F. or as much as for 10 per cent high-test gasoline. In the case of the closed cup method 1.8 per cent petroleum ether lowered the flash point about 47 deg. or the same as for 7.5 per cent of high-test gasoline.

The decrease in the open cup flash points for the gasoline-kerosene mixture was somewhat over 1.3 times as much as the decrease in the burning point for the same concentration of gasoline. For example, 10 per cent low-test gasoline lowered the flash point 82.8 deg., whereas it lowered the burning point but 55.8 deg.; 10 per cent high-test gasoline lowered the flash point 88.2 deg. and the burning point 63.0 degrees.

In the case of the petroleum ether-kerosene mixtures the flash point was lowered just about twice as much

as the burning point, e.g., 3 per cent petroleum ether lowered the flash point 93.6 deg. and the burning point only 46.8 degrees.

The burning point curves are of about the same shape as the open cup flash point curves, showing that in the case of the high and low test gasoline-kerosene mixtures the burning points did not decrease at the same rate as each other. In making up mixtures, the order of addition did not affect results, though such a difference is possible for a time at least on a larger scale.

It is evident that the flash and burning points of kerosene are greatly reduced by small admixtures of more volatile petroleum fractions, such as gasoline, so that grave danger can easily result therefrom.

DISTILLATION TESTS OF FRACTIONS USED

In order that the oils used in this work may be identified the specific gravity was determined by the hydrometer method and distillation cuts of the oils obtained.

The distillations were carried out as prescribed in Technical Paper 166 of the Bureau of Mines, with the addition of reading the number of cubic centimeters

No stem temperature correction was necessary in the case of the distillation of the petroleum ether, since the last fraction boiled off at 103 deg. C. as recorded by the thermometer and the emergent stem began at 105 deg. C. in all cases.

The solid curve represents the distillation when stem temperature corrections have been applied. The dotted curves represent the distillation without stem temperature correction.

E. W. Dean in his report on gasoline distillation (Bureau of Mines Technical Paper 214, p. 29) plots the dry point on the 100 cc. ordinate. This is not exactly correct, since the dry point is always obtained before 100 cc., the initial volume of gasoline, has been received. Plotting this results in the curve ending in a sharper bend than it should. To obviate this error, we have plotted the actual dry point on the curve where it is observed and extended a straight horizontal dotted line to the 100 cc. ordinate in order to show where the curve would come had Dean's method of plotting been used. This actually represents approximate loss in distillation.

For convenience, the ordinates are labeled both in Centigrade and Fahrenheit readings.

FIG. 7. DISTILLATION CURVES OF THE OILS TESTED

distilled every 5 deg. rise in temperature as recorded by the thermometer as well as readings at every 10 per cent by volume.

The 250 cc. flask connected with the condenser was filled with 100 cc. of the oil measured in a 100 cc. cylinder. The same cylinder was then used as the receiving vessel. In the kerosene and gasoline distillation the flask was covered with an asbestos box; this being omitted in the distillation of the petroleum ether. Heat was applied so that the distillation proceeded at the rate of about 5 cc. per min., the entire distillation requiring about 25 min. The thermometer used in these distillations was the same as that previously described as being used for the open cup flash and burning point determinations. Besides applying the calibration correction, a correction was added for the emergent stem of the thermometer, varying up to 2.5 deg. C. Formula for corrections was obtained from "Physico Chemical Tables," Castell Evans, vol. 1, p. 126, J. B. Lippincott Co., Philadelphia, Pa. The condenser trough was filled with cracked ice to insure complete condensation. There were from 2 to 3 cc. of residue left in the flask at the end of each distillation. The results obtained by the distillation are shown in the tables and curves following. Fig. 7 contains all of the oils in order that a comparison may be made between them.

Temperature, Deg. C. Deg. F.	Kerosene, cc.	Low-Test Gasoline, cc.	High-Test Gasoline, cc.	Petroleum Ether, cc.

The Liability for Infections*

BY CHESLA C. SHERLOCK

THE workmen's compensation acts have brought many new problems as to their own liability before employers. Not only that, but they have caused no amount of uncertainty among courts as to just what this liability amounts to.

The compensation acts serve to secure the payment of compensation to workmen who are incapacitated by means of an accidental injury "arising out of and in the course of" the employment. This naturally limits the employer's liability somewhat, but at the same time it raises a point of controversy over what is meant by the term "accident."

The courts have decided, and with good judgment, that the meaning to be given the word accident shall be its ordinary and usual meaning and that it cannot be given a technical meaning if the ultimate purpose of the compensation acts is to be kept in mind and preserved. So, they have said that an accident is any unlooked for and untoward event happening within chance and without design or intention. If a workman suffers such an accident which arises through the employment and out of it, then he is clearly entitled to compensation.

But it is the fitting of specific cases that come up to the studied expression of the statutes and of judicial opinions that causes the real difficulty. For instance, the question of whether an infection is an accident or not has caused no end of litigation under the acts. It is a well-known fact that workmen engaged in certain occupations are constantly subjected to the hazard of infection. Those who work with paint and stains are in constant menace; those who work in refuse and debris are constantly in danger of experiencing blood poisoning, and those engaged in certain

other specific occupations are constantly subjected to the danger of infection through both the blood and the lungs by reason of the materials they work with, the fumes they breathe, or the inherent nature of the work. The long list of cases being reported each year on this subject alone is ample authority for this statement.

In the earlier days of the compensation practice the courts were called upon almost in the first cases to decide whether or not diseases were accidents. They held in diverse opinions that they were and they were not accidents. These decisions have since given rise to a series of rules which are more or less authoritative and which embody the present law upon the subject.

Unless specifically provided for in the statute, an occupational or industrial disease is not an accident within the meaning of the compensation acts. As to what constitutes an occupational disease there may be some doubt, but the courts have pretty well defined it.

One authority states: "An occupational disease is a disease caused by or especially incident to, a particular employment."

In a New York case, the court said: "An accidental injury . . . is clearly distinguishable from an injury in the nature of a vocational disease, sustained in the course of the employment, where, from the inherent nature of the work, disease is likely to be contracted."

TRAUMATIC DISEASE

It is well known that where certain work is followed certain diseases are very apt to be contracted if the workman persists in following that employment very long. Among the most common of these diseases are various forms of poisoning such as lead and copper poisoning. Since these diseases are of an inherent danger to the work, the courts have almost uniformly held that they are not an "accident" and the workman is not entitled to compensation,

*Other articles by this author on the same general subject have appeared in *CHEM. & MET. ENG.* as follows: "The Explosion of Chemicals—Common Law Liability," Vol. 21, No. 2, July 15, 1919, p. 83; "The Explosion of Chemicals—Workmen's Compensation Acts," Vol. 21, No. 3, Aug. 1, 1919, p. 131.

unless the act specifically mentions occupational diseases, in case he suffers from one.

The rule, however, is different in Massachusetts and other States where the compensation is payable not for accidental injuries, but for "personal injuries." The court of Massachusetts has said that an occupational disease is a personal injury within the meaning of the Massachusetts act. This does not say, however, that all diseases are deemed to be non-compensable in the opinion of the courts. While occupational diseases are excluded because they form a distinct class of their own, there has been a clear reservation on the part of other, ordinary forms of diseases.

The rule is well settled that if the disease is clearly the result of the employment, or that the employment subjected the workman to a greater hazard to the disease than he would have been subjected to in ordinary employment, or if the disease resulted from an accidental injury, then the workman will be entitled to compensation. This is what is known as the "traumatic disease" theory. If the disease has its origin in trauma, or injury, then it is clearly an accident within the meaning of the acts. For instance, a workman falls off a trestle or a train of cars and because of his injuries and bruises about the chest contracts pneumonia. This is a compensable disease within the meaning of the compensation acts.

Or, another illustration: A workman is required to work for several hours in cold water in order to save a levee or other property of his employer from damage or destruction. Because of the unusual exposure he contracts pneumonia. This is a compensable disease within the meaning of the compensation acts.

INFECTION CASES MORE DIFFICULT

Still another case might be given: A workman is required to clean up debris following a wreck. He scratches his hands and contracts blood poisoning from handling the debris and refuse matter. This is a compensable disease within the meaning of the compensation acts.

Infection, because of its nature, is often a harder matter to determine than a mere disease. An infection, being of such slow and insidious origin that it is extremely difficult to trace it, presents an entirely different problem than an ordinary disease, the symptoms of which generally have their root in some event or happening within the employment. A workman may be able to determine, from his exposure and the like, where he got his disease, but not be able to state just where he got his infection.

It is necessary, however, that the infection be linked up to the employment by some certainty as to time and place and the circumstances under which it was acquired. Generally, employers resist claims for blood poison, for instance, unless the workman reports every little scratch and cut he receives at the time. It is so easy for one to pick up such infections outside the employment that employers are certainly justified in taking these steps for self-protection.

Where the employment is clearly to blame for certain infections, however, the courts will not be too technical in their requirements. In one case a workman employed to mow weeds along a right of way contracts poisoning on his hands and face. He was

allowed compensation, it not being necessary for him to prove specifically the exact instance when he encountered the poisonous substance which incapacitated him.

The compensation acts are administered in a "spirit of true helpfulness" whenever possible, and they will include infections and diseases within the limitations mentioned above.

Ammonia in Producer Gas*

By F. K. OVITZ

Assistant Chemist, Bureau of Mines

THE tests described in this paper were made at factory No. 2 of the Hazel-Atlas Glass Co., Washington, Pa., in co-operation with Mr. C. E. Frazier and Mr. C. D. Smith of that company. The object of the tests was to determine the amount of ammonia in gas from producers of the Smith type. At the time the tests were made the importance of ammonia for munitions, refrigeration and agriculture made it desirable that all possible sources of supply should be utilized.

For ammonia-recovery, gas-producers can be divided into two general classes.

1. Producers gasifying the fuel at a low temperature with a comparatively large amount of steam, 3 to 4 lb. of steam per lb. of coal.
2. Producers gasifying the fuel at a high temperature and using a comparatively small amount of steam, about 1 lb. per lb. of fuel.

From the first, or Mond type, 15 to 20 lb. of ammonia, (NH_3) , or 60 to 80 lb. of ammonium sulphate, $(\text{NH}_4)_2\text{SO}_4$, can be recovered per ton of bituminous coal. Information on the quantity of ammonia in gas from the second type, to which the Smith producer belongs, was not available.

DESCRIPTION OF TESTS

The producer plant consists of five producers with inclined grates, each grate having a projected area of 200 sq.ft. The coal is fed into the top of the producer through hoppers which are arranged so that they will distribute it uniformly over the top of the fuel bed. The thickness of the fuel bed during the tests was about 5 feet. The bed was kept in good condition and as free as possible from holes by hand-poking.

The coal used was from the Pittsburgh bed in Washington County, Pa., and contained about 1½ per cent of nitrogen on the moisture and ash-free basis. The size was not uniform; at times fairly clean coal of No. 1 nut size was used, while at other times a large amount of fine coal was mixed with it.

Air saturated with steam at 150 to 160 deg. F. was used to gasify the coal, about 4 lb. of air and 1 lb. of steam being used for each pound of coal. The gas was cleaned before being used. From each producer the gas passed through a "hot pipe" into a "down-comer," from which it entered the bottom of a primary scrubber, where it was cooled to about 140 deg. F. by water sprays. From the top of the primary scrubber the gas passed into a large header, where gas from all the producers mixed to some extent. From this header it was sent by exhausters through the tar filters and finally through the secondary scrubbers, where it was washed with water again and cooled to about 100 deg. F. and then delivered into the gas main.

*Published by permission of the Director of the Bureau of Mines

The water used in the system was cooled in a spray pond and recirculated. The water and tar from the scrubbers and that collected in the header ran into a common drain which emptied into the tar well, where tar was separated from the water. The water was pumped from the tar well to the spray pond, where it was cooled and then returned to the scrubbers.

Gas from a single producer was used for most of the tests. For total ammonia in the gas an open-end sampler was placed in the "hot pipe" about 5 ft. from where the gas left the producer. The sample of gas was passed through the following system to absorb the ammonia and measure the volume:

1. Bottle which served as a trap for condensed water and tar.
2. Four wash-bottles containing dilute sulphuric acid.
3. Filter made from asbestos fiber.
4. Experimental wet meter.

Suction was supplied by a small steam aspirator. The first two tests showed that it was very important to collect all the water which condensed from the gas because a considerable part of the ammonia was dissolved in it. For this reason in subsequent tests bottle No. 1 was arranged so that moisture and tar which condensed in the sampler could drain into it. To determine volatile and fixed ammonia, distilled water was used in the wash bottles in place of dilute sulphuric acid. Gas was drawn through the apparatus at a rate of about 1 cu.ft. per hour.

The liquid from all the bottles was made up to a definite volume. The ammonia in an aliquot part of this volume was determined by adding strong caustic soda solution, distilling and absorbing the ammonia in a measured volume of standard decinormal sulphuric acid. The acid which was not neutralized by ammonia was titrated with standard decinormal caustic soda using cochineal as indicator. The quantity of ammonia per ton of coal was calculated from the results of the titration and the volume of gas produced, by means of the formula given below. While no exact measurement of the quantity of gas produced per ton of coal could be made, 130,000 cu.ft. is assumed for the purpose of making the calculations and is believed to be sufficiently accurate for practical purposes. The weight of ammonia multiplied by 3.8787 gives the weight of ammonium sulphate per ton of coal.

$$\frac{\text{cc. of N/10 acid} \times 0.0017 \times 130,000}{\text{cu.ft. of gas in sample} \times 453.6} = \frac{\text{lb. NH}_3 \text{ per ton}}{\text{of coal}}$$

The quantity of ammonia in the gas at various points

in the system is given in Table I. All gas volumes are expressed in cubic feet at 60 deg. F. and 30 in. of mercury. Tests Nos. 1 and 2 were made with a large tar filter in front of the wash bottles and the results given on these are low, due to condensation of water vapor from the gas and absorption of ammonia by it. These results should not be used in computing averages. Tests Nos. 7, 9, 10, 11, 12 and 13 were made with distilled water in wash bottles in order that the proportions of fixed and volatile ammonia can be determined.

In addition to the quantity of ammonia in the gas, the percentage of ammonia in the liquor from the tar well and spray pond was determined. The results of these determinations are given in Table II.

An average of 5.70 lb. NH_3 , or 22.11 lb. ammonium sulphate, was found in the raw gas as the result of seven tests. While the variation between individual tests was quite large, it was no greater than might be expected on account of the changing conditions in the producers during the time tests were being made.

TABLE II. AMMONIA IN LIQUOR FROM TAR WELL AND FROM SPRAY POND

Liquor	Specific Gravity at 15 Deg. C.	Free NH_3 per Cent by Weight	Total NH_3 per Cent by Weight
Tar well.....	1.018	0.057	0.614
Tar well.....	1.017	0.072	0.732
Spray pond.....			0.687

No detailed study was made of the effect of these changing conditions on the amount of ammonia in the gas, but by watching the variations which occurred in the experimental results and the condition of the producer, it was apparent that the temperature in the top of the producer was a very important factor. The rate of gasification and the amount of steam used, within the limits of daily variation, did not affect results noticeably. Whatever effect these factors had was less than that due to the temperature of the top of the producer.

The temperature in the top of the producer appeared to be influenced by the condition of the fuel bed more than by any other factor. If the fuel bed was not kept free from holes, unconsumed air passed through it and the oxygen burned with gas in the top of the producer, thereby raising the temperature. It required almost constant attention to keep the fuel bed free from holes, and at times it was impossible to do so. Since high temperatures are unfavorable to the formation and production of ammonia, it is very necessary to maintain as low a temperature as possible in the top of the producer

a Tests 1 and 2 made with large filter, not used in calculating average results.

b Test made with distilled water in wash bottles.

in order to obtain the best yield of ammonia. The quantity of ammonia found in the gas from one ton of coal was of the same general magnitude as is obtained from the carbonization of one ton of coal in a retort or by-product coke oven. This seems to indicate that the ammonia obtained comes from the destructive distillation of the coal taking place at the top of the fuel bed, and that very little comes from nitrogen liberated during gasification of the fixed carbon. If ammonia is formed from nitrogen liberated during gasification of the fixed carbon, it is apparently broken up by the passage through the hot fuel bed before reaching the top.

Between 20 and 25 per cent of the total ammonia is in the form of fixed ammonia salts and the remainder is in the form of volatile or free ammonia.

Practically all of the fixed ammonia is absorbed in the water used for scrubbing the gas and accumulates in the pond liquor. Most of it is absorbed before the gas reaches the secondary scrubber, as shown by test No. 12. At the time of the tests the quantity of ammonia in the tar well and pond liquor averaged 0.678 per cent by weight, practically all of it being fixed ammonia. This percentage varies from day to day with the quantity of water in the pond. When fresh water is added to the pond to make up for loss by evaporation, the percentage decreases temporarily, but the total quantity in the pond increases steadily in proportion to the volume of gas scrubbed by the liquor.

Practically all of the volatile ammonia is absorbed in the scrubbing water and later dissipated into the air at various points throughout the system. Tests Nos. 9 and 11 show that the cleaned gas contained only about 0.4 of a pound of ammonia per ton of coal, practically all of which was in the volatile form. The exact distribution of the volatile ammonia was not determined. It depends upon the temperature of the scrubbing water at different points in the system and varies from day to day with the changes in these temperatures and the quantity of water.

It is possible to recover practically all of the ammonia in the gas, either by cooling sufficiently and scrubbing with cold water, or by treating with sulphuric acid. However, because of the low concentration of the ammonia in the gas, less than one-tenth that of by-product oven gas, and the large volume that consequently must be treated per lb. of ammonia recovered, the cost of equipment and recovery would be high. For example, to obtain the ammonia from one ton of coal used in a gas producer, about 130,000 cu.ft. of gas would need to be treated, whereas if the coal were used in a gas retort or by-product oven, about 10,000 cu.ft. would have to be treated and the quantity of ammonia recovered in both cases would be approximately the same. The fixed ammonia, amounting to about 1.25 lb. per ton of coal, can be recovered by distilling the pond liquor with lime.

House Passes Tungsten Protection Bill

On Aug. 21 the House of Representatives passed the Timberlake bill providing for a tariff of \$10 a unit on tungstic oxide, which amounts to \$10 a ton on crude tungsten. Manufactured tungsten products must pay twice the amount, or \$1 per lb. This tariff, in addition to the estimated import price of \$8 to \$10, will fix American tungsten at \$18 to \$20 and thus enable domestic producers to compete with imported ore from China and South America, upon which there is no tariff at present.

Recent Chemical and Metallurgical Patents

Complete specifications of any of the United States patents abstracted herein may be obtained by remitting 5c. each to the Commissioner of Patents, Washington, D. C.

Utilization of Tin Scrap.—A method of separating iron and tin based upon the fractional distillation of their chlorides is employed by DANIEL A. and SIDNEY H. WILCOX of Garden City, N. Y., for the utilization of tin scrap. The scrap is compressed and heated in a suitable furnace to such a temperature that a vigorous reaction ensues when chlorine is passed over the metal, both metals being volatilized as chlorides. Or, the scrap may be melted and the chlorine passed through or over the melted metal contained in a bessemer converter, reverberatory, cupola or blast-furnace, electric melting furnace or muffle furnace. In either case, the mixed chlorides are separated by fractional condensation. The tin chloride may be converted into metallic tin or tin oxide by well known methods. The ferric chloride is dissolved in water, reduced to ferrous chloride by passing the solution over hot iron and electrolyzed, using insoluble electrodes, so that the products are pure iron (some occluded hydrogen is present, but this may be removed by heat) and chlorine gas, which may be utilized for the treatment of additional quantities of scrap. (1,310,381; July 15, 1919.)

Method of Producing Lead Salts.—RALPH M. HARRINGTON has developed an electrolytic method for producing white lead and other lead salts. White lead similar to that produced by the "Dutch process" may be produced in the apparatus here illustrated. A cell (1) with anode (2) and cathode (3); the

DIAGRAM SHOWING ELECTROLYTIC METHOD OF PRODUCING LEAD SALTS

cathode is surrounded by a diaphragm (5). The anolyte is a solution of sodium acetate, the catholyte contains in addition sodium hydroxide, carbonate and bicarbonate. The passage of a current through the cell produces lead acetate at the anode and sodium hydroxide at the cathode, thus, $2\text{Na}(\text{C}_2\text{H}_3\text{O}_2) + \text{Pb} = \text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 + 2\text{Na}$ and $\text{Na} + \text{H}_2\text{O} = \text{NaOH} + \text{H}$. The catholyte is circulated by the pump (15) to a carbonating tower (16), where it meets a current of CO_2 . The NaOH produced at the cathode and this

Synopsis of Recent Chemical and Metallurgical Literature

Manufacture of Synthetic Salicylic Acid.—An extremely practical description of the modern process for the manufacture of salicylic acid was given in a recent issue of the *Chemical Age*¹ by E. P. Wightman and George Robinson. Out of the many possible methods of synthesis, only two have achieved commercial success—the Kolbe and the Schmitt processes, which involve the following reactions:

1. The formation of sodium phenate from phenol:

$$\text{C}_6\text{H}_5\text{OH} + \text{NaOH} = \text{C}_6\text{H}_5\text{ONa} + \text{H}_2\text{O}.$$
2. The phenate combines with carbon dioxide to give either

(a) sodium phenyl carbonate or

(b) o-carboxylsodium phenolate or some of both:

3. The transformation of either of these into their isomer, sodium salicylate:

4. Any unchanged or reformed sodium phenolate (by reversal of reaction 2a) combines with the sodium salicylate to form disodium salicylate and phenol:

5. The free acid is precipitated from a solution of its sodium salt by hydrochloric acid:

The Kolbe synthesis requires a high temperature but works under atmospheric pressure. The disadvantages are that, under these conditions, reaction 2a goes from right to left and thus a large percentage of phenol remains unconverted (see equation 4). However, at least one large plant in this country is employing it with apparent success.

In the Schmitt process, the reversal of reaction 2a is prevented by increasing the active mass of carbon dioxide present. Pure sodium phenate is first prepared by melting an amount of U.S.P. phenol equivalent to 236 lb. 100 per cent phenol and stirring it into a hot solution of 100 lb. of 100 per cent caustic soda in 19 gal. of water contained in a jacketed autoclave, which must be made of bronze if the chemical method of purification (see below) is to be used. The phenate solution is evaporated under diminished pressure and finally dried to a fine powder, which must be perfectly dry, as the slightest trace of moisture will vitiate the results. After cooling, carbon dioxide is allowed to enter until the inside has attained atmospheric pressure and then at such a rate that a pressure of 10 lb. is reached within an hour. The temperature must be kept below 50 deg. C., since the

reaction is exothermic. During the next hour the gas pressure is raised slowly to 100-110 lb. and the temperature to 130 deg. C. As soon as all the phenylcarbonate has been isomerized to salicylate, the partial (dissociation) pressure due to the phenylcarbonate disappears and the gage pressure registers a temporary drop. (The dissociation pressure of sodium salicylate is only 143 mm. at 220 deg. C., while that of sodium phenylcarbonate is greater than one atmosphere at 85 deg. C.) The gas pressure is cut off and, after heating for another hour, the mass is cooled and dissolved in hot water. The yield of crude sodium salicylate is from 98 to 99 per cent of theoretical.

There are two general methods of purification—the steam distillation, or physical, method and the precipitation, or chemical, method. For the first method, the free acid is precipitated from a hot solution of the crude sodium salt by adding 1 to 1 sulphuric acid, cooling and filtering. The acid precipitated cold is amorphous, is very difficult to centrifuge and holds water tenaciously. The acid is melted in an oil-heated still and distilled at a temperature of about 175 deg. C. by means of superheated steam. The condenser must be made of some non-ferrous alloy.

The product is a fluffy, white, needle-like crystalline acid with a faint odor of phenol (due to slight decomposition during distillation), which may be removed by washing with cold water in a centrifuge.

The chemical method employs stannous chloride as follows: In the purification kettle (preferably glass enameled, steam jacketed and provided with a stirrer) some of the solution of crude sodium salicylate is made faintly acid with C.P. sulphuric acid, heated to 90-100 deg. C. and treated in succession with:

(a) A solution of stannous chloride containing 2 to 3 per cent of tin salt by weight of the salicylate.

(b) Flake or powdered aluminum 1 to 1½ per cent. (This may or may not be used.)

(c) Acid-washed bone or blood charcoal (free from phosphates and iron); about 4 per cent.

(d) Concentrated sodium carbonate solution until neutral to litmus. If the solution remains either acid or alkaline, tin or aluminum or both may be carried through to the final product.

Filter hot through a filter press into a precipitating tank, which contains 1 to 5 sulphuric acid. Cool, centrifuge and wash in centrifuge with cold water until free from soluble salts. During the whole of the purification process, the solution must not come in contact with iron. The yield is 94 to 95 per cent theoretical, whereas the steam distillation rarely yields more than 90 per cent. The acid is dried on shelves in a room through which warm dry air at not over 60 deg. C. is drawn.

EDITOR'S NOTE.—The importance of salicylic acid as a dyestuff and medicinal intermediate is shown by the fact that 3,270,462 lb. of the U.S.P. grade, valued at \$2,706,171, was produced by 13 firms in 1918. During the same period, eleven firms produced 1,395,630 lb. of the technical grade, valued at \$799,337. The most important derivatives of salicylic acid used medicinally are: the sodium salt, acetyl salicylic acid (aspirin), phenyl salicylate (salol) and methyl salicylate. As a dyestuff intermediate, salicylic acid is used in the manufacture of alizarine yellow G (m-nitrobenzene-azo-salicylic acid) and other dyes which were used in large quantities during the war for the production of khaki.

Electric Production of Carbon-Free Alloys

By E. F. NORTHRUP

AMETHOD is now available and commercially perfected whereby any metal or alloy in granular form, in small broken pieces or in solid masses can be melted absolutely free from carbon and all other chemical contamination, provided this metal fuses at a temperature under the fusion temperature of pure zirconia.

The apparatus needed is a source of high-frequency current of 10,000 cycles per second or over, and a special type of induction furnace. This source of high-frequency current, in power units from 1 up to 100 kw., has been developed in the oscillatory current system which

FIG. 1. CROSS-SECTION VIEW OF SCHEME OF FURNACE

forms the major portion of the Northrup-Ajax high-frequency induction furnace. The complete theory of this method of electric heating by high-frequency induction has been given in a paper by the writer, presented at the April 3 to 5, 1919, meeting of the American Electrochemical Society.

The special type of induction furnace required for obtaining carbon-free melts is the subject of this brief sketch and is indicated in one of its forms diagrammatically in Fig. 1. This diagram is almost self-explanatory. The tremendous concentration of energy produced by inductive action in a comparatively small volume makes it necessary to maintain the inductor coil cool by artificial means. To accomplish this cooling in a simple and effective manner, the material used for winding the inductor coil is a thin-walled, flattened copper tubing. It is flattened and wound edgewise to obtain the maximum possible number of turns to the inch. A small flow of water through this tubular coil maintains it always at the temperature of the tap water used.

The melt, which is located within the inductor coil and which may be only $\frac{1}{2}$ to 1 in. less in diameter than the inside diameter of the coil, may be raised to a temperature of 2500 or 2800 deg. C., the coil remaining under 20 deg. C.

The procedure in making a melt of any electrically conducting material, such as electrolytic iron or nickel with which other metals are to be alloyed, is as follows:

A thin-walled crucible or open cylinder of fire-clay, magnesite, zirconia or like material is formed. This is located centrally in the inductor coil and the space outside and under this cylinder is filled in with fine

alumina, silica or zirconia sand. The metal or component parts of the alloy to be produced is broken into small pieces, preferably about the size of walnuts, and packed in the thin-walled cylinder. When the high-frequency current is passed through the inductor coil rapid heating begins at once. This heating is due solely to the enormously large eddy currents which flow in the small conducting masses of the product being heated.

Melting of pure iron in lots of 2 to 5 lb. begins in from 10 to 20 min. and high super-heat is reached in 25 min. When the mass has become completely molten, more material may be dropped in. The melted mass does not leak even though the thin-walled container cracks and breaks, for this is imbedded in a mass of sand which makes a natural metal-tight pocket. As soon as the mass becomes molten a very useful and interesting phenomenon is noted. The surface of the molten mass becomes much agitated and the central region of this surface is raised a considerable fraction of an inch above its circumferential region. The metal or alloy is in fact subjected to a vigorous stirring action. Metal flows vertically upward in the axial region and downward in the circumferential region, and thus an alloy becomes automatically most thoroughly mixed. This stirring action is not a thermal phenomenon, but is caused solely by the action of the electromagnetic forces. Its importance is easily recognized when a perfect mix of the constituents of the alloy is desired.

The following results are readily obtained in this method of heating:

1. All conducting materials may be raised to 2500 or 2800 deg. C. or to their vaporization temperature in

MICROGRAPHS OF CARBON-FREE ALLOYS OF ELECTROLYTIC IRON. X 75

75% Cu = 25% Fe	25% Cu = 75% Fe
95% Fe = 5% Mo	92% Fe = 8% Cu

an oxidizing atmosphere. Platinum is easily melted in this way.

2. By placing the inductor coil on the outside of a quartz tube which is closed at both top and bottom, melts may be made in any atmosphere or in vacuum.

3. In the open type of furnace, the molten metal can be drawn off from the bottom into a mold.

4. The quantity of metal, Ni, Fe, Pt, etc., which

can be handled at a single melt is determined wholly by the size of the furnace employed and the power available. An inductor coil of 40 turns, 6 in. long by 3½ in. inside diameter, supplied with 10 to 20 kw., will melt 4 lb. of electrolytic nickel or iron at a charge in from 20 to 30 min. Larger furnaces supplied with larger power will handle larger quantities.

Palmer Physical Laboratory,
Princeton, N. J.

A New Compensated Heatmeter

By CHARLES P. FREY,

Chief Engineer, Brown Instrument Co., Philadelphia, Pa.

UNTIL comparatively recently the determination of furnace and kiln temperatures by means of thermocouples was attended with complications and difficulties which made practical men impatient and in some instances doubtful in regard to the intrinsic value and reliability of the method. Technical men, however, have realized from the beginning that, within certain temperature limitations, the results obtained by the use of thermocouples were not only accurate, but could be made "direct reading," provided the thermocouple be connected with a galvanometer which would indicate the actual value of the e.m.f. obtained by heating.

On first consideration, this problem did not seem difficult of solution, since it is an established fact that the e.m.f. or voltage of a thermocouple bears a direct relation to the difference in temperature between its hot and cold ends. It is also true that the movable coil of a millivoltmeter will be deflected to an extent which is directly proportional to the e.m.f. of the thermocouple. Therefore it would seem the simplest operation imaginable to connect the thermocouple and the instrument by insulated conductors, figure the scale in temperature values, and regard the problem as solved.

Unfortunately, however, we have also to contend with factors which cannot be ignored if accurate results are required; namely, line resistance, thermocouple resistance and the resistance of the indicator itself; because, to be precise, a direct current millivoltmeter actually is not a millivoltmeter at all, except in name, but is a milliammeter or current indicator. All instruments of the d'Arsonval type depend primarily upon current for their operation, and the extent of the deflection obtained with any given current is established by the intensity of the magnetic field, the controlling force of the springs and the number of convolutions or ampere turns in the movable coil, and not by a remote e.m.f. Therefore, if the conductors which carry the current from the source of e.m.f. to the terminals of the instrument do not have a negligible resistance, then, in accordance with Ohm's law, there will be an appreciable fall of potential along the line, with the result that the movable system will receive a diminished current, and therefore be low in its readings. To reduce such errors to a minimum, it is desirable that the instrument resistance be as high as possible, so that the line and thermocouple resistance may be proportionately insignificant.

For instance, when this is not the case: If the resistance of the millivoltmeter *M* (Fig. 1) is 300 ohms and the resistance of the line *A* and thermocouple *C* is 3 ohms, the current through the circuit will be reduced practically 3 parts in 300, or 1 per cent, and the instrument indications will be 1 per cent low. Figured in degrees Fahrenheit, this would mean an error of ap-

proximately 14 deg. in 1400 deg. F., if a thermocouple were used.

The advantage of high-resistance instruments, therefore, becomes evident. For instance if the pyrometer has a resistance of 600 instead of 300 ohms, and the line resistance remains the same, an error of 3 parts in 600 will result, or only ½ of 1 per cent instead of 1 per cent, or about 7 deg. F. in 1400 deg. F.

Until within the last five years it was customary to use a so-called low-resistance pyrometer to measure the current from the thermocouple. These instruments had from 2 to 5 ohms internal resistance and were naturally materially affected by the external resistance of the thermocouple and leads. In the past few years high resistance pyrometers have been almost universally adopted. These instruments have an internal resistance of usually from 300 to 1200 ohms. The higher the resistance, naturally the less the effect on the readings due to variations in line resistance. But with increase in internal resistance, something had to be sacrificed, and usually control or torque is weakened. In consequence, the instrument is not as substantial or dead beat, and, due to the use of lighter springs, is more apt to be affected by spring fatigue.

It has been found by trial that an instrument of medium resistance (about 300 ohms) can be produced in a satisfactory and substantial form, but an instrument of this class is necessarily affected in its indications when leads of considerable length are employed. Material variations in the length of thermocouples are also a source of error, as well as the introduction of compensating leads. When compensating leads are employed, as well as long wires, in connecting the thermocouple with the instrument, it is a common practice to reduce the resistance of the instrument in order to offset the effects of line resistance. This is at best a method of doubtful value, since it interferes with checking the scale by comparison with a standard, and does not compensate for changes in the resistance of the line or thermocouple, due to variations in temperature.

Various devices and attachments have been made for use in connection with indicating and recording millivoltmeters and pyrometers, by means of which the instruments will remain direct reading, and at the same time be compensated for external or line resistance. Inventions of this class range all the way from a simple step rheostat connected in series with the "dead" resistor of the instrument to the elaborate and complicated apparatus employing the substitution and deflection methods, the potential of the thermocouple being first balanced against another potential derived from a dry cell; and after an intermediate operation and an inter-comparison of deflections, the effect of line resistance is finally balanced out by a rheostat, and direct deflections are obtained from the thermocouple current.¹

It remained for two physicists² of the Bureau of Standards, Washington, to offer an invention of theirs, which, incorporated in a Brown pyrometer, eliminates the effect of line and thermocouple resistance by means of an operation which is so simple that anybody can use the instrument and obtain accurate results. This improved heatmeter will unquestionably appeal to the practical man who wants results and does not care especially how the instrument functions, provided its indications can be relied upon.

¹The Brown precision heatmeter.
²Paul D. Footé and T. R. Harrison.

In testing with this apparatus all that is necessary is to connect the thermocouple with the instrument binding posts in the usual manner, press a button, turn a knob and take a reading, which will be the correct e.m.f. of the thermocouple at its hot end, even if the line is miles in length. In fact, the line may have as much as 15 ohms resistance.

For those who would like to understand the fundamental principle of the Harrison-Foote invention, and at the same time prefer a simple demonstration, the following explanation should be of interest, especially since it reduces the method to its most elemental form by substituting an ammeter in place of a pyrometer, and using cells instead of a thermocouple.

If *A* (Fig. 2) is an ammeter of negligible resistance in series with three resistors of 11, 8 and 11 ohms respectively, and an e.m.f. of 6 volts is impressed by a battery, also of negligible resistance, it is evident that the resistance in circuit will be $11 + 8 + 11 = 30$ ohms, and by Ohm's law ($C = E \div R$) the current

But it is obvious that, since R^2 and R' are alike in resistance, the current in splitting at *P* will divide evenly, half of it passing through the ammeter. Therefore the ammeter will indicate only one-half of the total current, or 0.2 amp., the same as in Fig. 2. Hence, under these conditions the deflection of the ammeter will not be changed whether the plug is in or out. If, however, 10 ohms of line resistance is added to the circuit (see Fig. 4) the current with plug out will be $6 \div (11 + 8 + 11 + 10) = 0.15$ ampere.

With plug in, R^2 is cut out as before, and the total resistance will be

$10 + 11 + (8 \times 8) \div (8 + 8) = 25$ ohms,
and the current will be

$$6 \div 25 = 0.24 \text{ ampere.}$$

Of this current, one-half, or 0.12 amp., will pass through the ammeter. Its deflection will hence be less than in Fig. 2 when the plug is inserted, and the ammeter pointer will move down scale. To remedy this, let R^2 be in the form of a rheostat (Fig. 5). Then if the

Fig. 1

Fig. 3

Fig. 5

Fig. 2

Fig. 4

Fig. 6

throughout the circuit will be $6 \div 30 = 0.2$ amp. and the ammeter will indicate accordingly.

If now (Fig. 3) a plug is inserted in *P*, the resistor R^2 will be short-circuited. By the same operation, the resistor R' , which also has a resistance of 8 ohms, will shunt or "by-pass" the ammeter, thereby robbing it of part of its current. In other words, the current splits when it reaches the plug, part of it going through R^2 and the ammeter, and the remainder through R' , reuniting at *p* and passing through R^1 , back to the battery.

The total current in this case will, of course, depend upon the total resistance in circuit. Since R^2 is cut out, the resistance will be

$R^1 (= 11 \text{ ohms}) + R^2 + R^1$ (R^2 and R^1 are in parallel).
By the law of divided circuits, the resistance of R^2 and R^1 will be their product divided by their sum, or

$$(8 \times 8) \div (8 + 8) = 4 \text{ ohms}$$

the total resistance being 15 ohms and the current being $6 \div 15 = 0.4$ amp., twice the current flowing in Fig. 2.

resistance of this rheostat is reduced an amount equivalent to the 10 ohms of line resistance, the conditions prevailing in Figs. 2 and 3 will be re-established, the line resistance will be compensated for, and the pointer will again indicate 0.2 amp., with plug in or out; all of which is very simple and self-evident after it has been demonstrated and explained.

In the actual construction of the instrument for technical and practical use, the movable system consists of a highly sensitive copper or aluminum wire coil suitably mounted in an intense magnetic field. In place of the plug *P*, a three-way press button is used. The shunt R^1 need not, of course, have a resistance equal to that of R^2 ; in fact it is preferable so to proportion it that the current through the circuit as a whole may be increased eight to ten times. The deviation of the pointer from normal will hence be large for even a very slight change in line resistance, permitting easy adjustment.

In practice the rheostat R^1 has a resistance of 15 ohms, subdivided into steps of approximately 0.05 ohm,

so that the position of the pointer may be regulated with absolute exactness. In this connection it is in order to call attention to the fact that, while it is, of course, desirable to know what the range of the rheostat is, it is not at all necessary to know or attempt to determine what the line resistance may be. The rheostat is normally set at zero and, in testing for line resistance, is given a clockwise motion. In an experimental model the following proportions were adopted with excellent results (see Fig. 6).

Total resistance for 10 millivolts, 290 ohms
Current without plug, 0.000138 ampere.
Current with plug, 0.00106 ampere.
Resistance of shunt, 26.25 ohms.
Movable system, 53.3 ohms, copper wire coil.
Rheostat, 15 ohms.

The temperature coefficient of the instrument was $+0.000365$ deg. F. It is, of course, possible to construct these heatmeters with much higher resistances to meet special requirements, but excessively high values in ohms per millivolt are not factors of first importance in this type of pyrometer.

As already stated the shunt R' need not have a resistance equal to that of R^2 , which is proved by the appended demonstration in which the following notations are employed:

R^3 = Maximum or "zero" position of rheostat.
 R^2 = Resistance of ballast coil.
 R^3 = Resistance of swamping coil and movable system in series.
 R^4 = Resistance of shunt.
 RL = Line resistance.
 Rt = Sum of line resistance and resistance of rheostat when it is in any given position.
 I = Current flowing through movable system.
 E = e.m.f. of thermocouple at any given temperature.

In adjusting the instrument circuits at our laboratory, the resistors are so proportioned that

$$R^3 \div R^2 = R^3 \div R^4$$

The scale is graduated so that the instrument will give correct readings when

$$Rt = R^4$$

Assuming the instrument to be connected as in Fig. 6, and with plug out, then

$$I = E \div (R^2 + R^3 + Rt)$$

When the plug is in, the total current becomes

$$E \div [(R^3 \times R^4) \div (R^2 + R^4) + Rt]$$

Since the resistance of a divided circuit (the swamping coil and movable system in shunt with R^4) is the product of the individual resistances divided by their sum, this current will proportion itself in the two arms of the divided circuit in inverse ratio to their resistances. Therefore

$$I \left[\frac{R^4}{(R^3 + R^4)} \right] \left[E \left(\frac{R^3 \times R^4}{R^2 + R^4} + Rt \right) \right]$$

Or, simplifying

$$I = R^4 E \div (R^2 \times R^4 + R^3 \times Rt + Rt \times R^4) = E \div (R^2 + \frac{R^3}{R^4} \times Rt + Rt)$$

The rheostat is adjusted so that this current equals the current obtained with plug out. Then

$$E \div (R^2 + \frac{R^3}{R^4} \times Rt + Rt) = E \div (R^2 + R^2 + Rt)$$

Therefore: $R^2 \div R^4 \times Rt = R^2$
or, $Rt = R^4 \div R^4 \div R^2 = R^4$

Since Rt now equals R^4 , the instrument will give correct readings.

It is in order to add that, while an experimental model has been referred to for data, the development of these instruments has long since passed the experimental stage, and, in practical form, the improved Brown heat-

meters, incorporating the Harrison-Foote method, have all of the following advantages:

They are direct reading throughout their entire scale range.

They require no dry cells or standard cells.

They are independent of line or thermocouple resistance.

They have a negligible temperature coefficient.

The operation of these instruments is simplicity itself. It cannot be questioned that such an instrument is a radical improvement on any of the various forms of electric pyrometers heretofore available and represents another noteworthy advance in pyrometry.

Production of Algin

Chemists throughout the country will be interested to know that the Hercules Powder Co. is devoting a good deal of attention to the extraction of algin from kelp. Algin is a substance whose properties are widely known, being a vegetable gum of extremely high viscosity. Its manufacture and use are on a firm footing in Europe, but so far the industry has never become well established in this country, largely, it is thought, because of difficulties in the way of securing a uniform supply of fresh kelp at a reasonable cost. The experience gained by the Hercules Powder Co. in harvesting kelp for the manufacture of war materials has overcome these difficulties as far as this organization is concerned.

There is a wide field of possible usefulness for algin. Algin compounds in general give an exceedingly vis-

cous solution, and for that reason their application as a sizing for textiles and paper, as a thickener for printing colors and as a proofing for interior walls and ceilings is at once apparent. The sodium compound of algin is soluble in water, a 5 per cent solution thereof being so viscous that it can hardly be poured from a vessel. The compounds of the heavy metals with algin are insoluble in water, some of them being soluble in ammonia, which solvent is used in their application as a waterproofing material in textiles.

AMERICAN METHODS IN FOREIGN TRADE, A GUIDE TO EXPORT SELLING. By George C. Vedder, ix + 204 pages. New York: McGraw-Hill Book Co., Inc.

The ability of a country to export a manufactured article or a product depends upon its quantity production in quantity more than sufficient for home consumption. The demand for any article is in the last analysis a function of its quality. The producer who gives most for value received acquires a business good-will which is the foundation upon which success is built. In competing in foreign markets the demand is in proportion to quality. Business success at home predicates success abroad, but there is the barrier of an international boundary and all that that connotes. The manufacturer who finds himself in the position to produce in larger quantities and requiring an extended market abroad will find in Mr. Vedder's book sound advice and authentic information gained through many years' intimate acquaintance with successful exporters. This book should serve as a guide in establishing a sound export selling policy.

Increased foreign trade is responsible for our more intimate association with other nations. It makes necessary certain phases of our Government's foreign policy. The chapters on the nationalization of foreign trade, foreign credits, American banks abroad, the merchant marine, reciprocity in foreign trade and the tariff are of interest to more general readers. They contain an analysis of the underlying conditions and the various factors which will broaden the reader's understanding in these matters.

L. W. CHAPMAN.

Personal

MR. ROBERT FOGELSON, formerly with the research division, Chemical Warfare Service, has accepted a position with the Newport Chemical Works, Inc., Carrollville, Wis.

DR. ELLIS I. FULMER, formerly of the faculty of arts, department of chemistry, University of Toronto, has accepted a position as assistant professor of chemistry, Iowa State University, Ames, Iowa.

MR. REGINALD E. HORE has resigned the editorship of the *Canadian Mining Journal* and is succeeded by Mr. F. W. GRAY, formerly associate editor.

COL. W. R. LANG has relinquished his duties in Military District No. 2 to resume his chair as head of the department of chemistry, University of Toronto.

MR. HAROLD N. LAWRIE, chairman of the Board of the Oregon Bureau of Mines and Geology, has accepted the active chairmanship of the Division of Precious and Rare Metals in the American Mining Congress.

MR. DORSEY A. LYON has been made chief metallurgist of the Bureau of Mines, vice Dr. Cottrell, in conjunction with the position of supervisor of stations.

DR. VAN H. MANNING of the U. S. Bureau of Mines was in San Francisco Aug. 15 to 18 on a tour of inspection of the Bureau's experiment stations.

DR. ARTHUR C. NEISH, who for the past twenty years has been on the staff of the department of chemistry, Columbia University, New York City, has accepted the chair of chemistry at Queen's University, Kingston, Ont., and will undertake his new duties with the opening of the university in October.

MR. ROBERT F. REED has resigned his position as superintendent of the Norwood, Ohio, dye plant of the Ault & Wiborg Co. to accept a position in the Deepwater Point, N. J., dye plant of E. I. du Pont de Nemours & Co.

DR. R. F. RUTTAN, head of the chemical department of McGill University, Montreal, was in England during July, where he attended the International Convention of Chemical Societies in London, July 15, as representative of the Canadian Society of Chemical Industry.

MR. JEROME D. STEIN, formerly control supervisor of the nitrate division, U. S. Nitrate Plant No. 2, Muscle Shoals, Ala., has accepted a position with the Gordon Dryer Corporation.

MR. JACK A. THOMAS has resigned his position as department manager of the chlorinated products section of the Rollin Chemical Co. because of ill health.

Current Market Reports

The Non-Ferrous Metal Market

Monday, Aug. 25.—During the past two weeks, only minor fluctuations took place. Prices in general have assumed a normal bearing with regard to production costs and consumption offers.

Aluminum.—Transactions are mainly by direct contract. The open market continues quiet; 98-99 per cent ingots are quoted at 33c. per lb. Scrap casting, 21 to 24c.; sheet scrap, 22½-25c., and clipping, 24 to 27c.

Antimony.—The market is easy; spot wholesale is quoted at 8½c. Job lots, 9c. lb.

Copper.—The market is firm with present quotations at 23½c. lb. and 24c. for the last quarter of the year.

Copper sheets, hot-rolled.....	lb.	33.50	
Copper sheets, cold-rolled.....	lb.	35.00	
Copper bottoms.....	lb.	41.50	
Copper rods.....	lb.	24.00	
Copper wire.....	lb.	25.00	
High brass wire and sheets.....	lb.	27.75

Low brass wire and sheets.....	lb.	30.50	
Low brass rods.....	lb.	31.25	
Brazed brass tubing.....	lb.	39.00	
Brazed bronze tubing.....	lb.	44.25	
Seamless copper tubing.....	lb.	37.50	
Seamless bronze tubing.....	lb.	40.00	
Seamless brass tubing.....	lb.	36.00	
Scrap, heavy machinery comp.....		17	18
Scrap, heavy and wire.....		17	18
Scrap, light and bottoms.....		15	16
Scrap, heavy, cut and crucible.....		18½	19½
Scrap brass, heavy.....		10	11
Scrap brass, casting.....		12	13
Scrap brass, light.....		9	10
Scrap, No. 1 clean brass turnings.....		10	11
Scrap, No. 1 comp. turnings.....		15	16

Lead.—The dual lead market continues, the smaller producers quoting at a slight reduction, New York 5.8-6c. and East St. Louis 5.5-5.75c. lb. Cut sheet lead is bringing 9c.

Tin.—The freed tin market did not drop to as low a level as expected because large stocks are not available. Straits spots are at 58c. and electrolytic, 55½c.

Zinc.—Spot spelter has advanced to 7.9c. in New York and 7.5c. East St. Louis. Sheet zinc, 10c. lb.

The Iron and Steel Market

The second half of August constituted a crucial period in iron and steel market history. Labor unrest became more and more manifest. Strikes were not infrequent. Some were settled with little difficulty, but many were not settled. A strong feeling was shown among manufacturers against granting demands of men, as demands had become unreasonable. In some instances plants were closed upon the initiative of the management, trouble being in sight. Where strikes were settled the settlements involved small or no concessions, and some strikes that were allowed to go their way could probably have been settled by granting small concessions. Apart and probably entirely dissociated from these sporadic strikes was the general effort of the American Federation of Labor to unionize the entire industry.

On Aug. 26 there was published a plain and strong statement by President Wilson to the effect that there would have to be a truce in the demands of labor, and calling upon every one to assent. It is too early, at this writing, to observe widespread effects from this enunciation of a policy calculated to stop the "endless chain" or "vicious circle" of alternating increases in cost of production and increase in commodity prices, but the effects will undoubtedly prove very important. A turning point is probably marked.

Just before this statement was made by the President there was nothing in sight but difficulties. There was a strong possibility that a strike would be called or that plants would be closed in anticipation of strikes.

LABOR TROUBLES DOMINATE MARKET

The iron and steel market was dominated by the prospects of labor troubles. Producers became very reserved in their selling policies and in most finished products withdrew from the market except as to orders from regular customers. The mills were moderately well sold, but certainly not oversold. They feared they would be unable to produce anything like full tonnages.

Buyers were likewise influenced by the labor situation and prospects. A few buyers were moved to curtail their purchases because they did not wish to buy material when the mill obligation to deliver was qualified by strike and other clauses. The majority of buyers were influenced to offer greater tonnages to mills. Specifications against contracts were heavy and new purchases were attempted. The occasional or chance buyer generally failed to secure acceptance of his proffered orders.

The labor unrest had another effect upon the market. It made it clear to all producers except a few whose mental attitude is not readily explained that it would be extremely unwise to attempt to advance any prices. In June the Steel Corporation had allowed it to become known that as a settled policy the corporation was opposed to price advances, this year at any rate, and that view eventually became general. With mills fairly well sold up price advances would not materially increase incomes for several months, while in all probability they would stimulate demands for increased wages. As there is no influence remotely tending toward the lowering of prices, the general price level could hardly be more effectively stabilized than it is at this time.

REAL CONSUMPTIVE DEMAND NOT KNOWN

An unfortunate feature of the stimulus given to demand by the fear that production would be reduced is that the market as it is seen does not necessarily reflect the real consumptive demand. It is not known that buyers are really in position to consume all the steel they have been clamoring for. It is to be noted on the other hand that as a rule steel demand is light during the two midsummer months, and particularly toward the latter part of August, when the advent of Autumn is so near at hand that there is an unusual disposition to postpone purchases. The two influences may have pulled in opposite directions, and the more settled labor conditions that may now be expected with a considerable degree of confidence may not have the effect of decreasing the pressure of any buyers for deliveries.

While prospects as to the production of iron and steel may be regarded as greatly improved by the strong call of the President for a truce in the matter of labor demands, the iron and steel industry still has a difficulty arising from labor conditions, that difficulty being that the consumption or employment of steel in construction work is discouraged by the high cost of erection due to high wages and indifferent performance of labor. Much construction work that investors have in mind is not coming to a head because prospects as to cost of the work are not sufficiently well defined. The monthly reports of the Bridge Builders' and Structural Society have shown steady improvement in the volume of fabricated steel contracts let, such lettings representing 24½ per cent of the fabricating capacity in April, 49 per cent in May, 65 per cent in June and 71 per cent in July, but it is not certain that August will be found to have shown much if any improvement, and to give this branch of the industry a proper start after the war there should have been lettings for a few months at far beyond the capacity.

AUGUST STEEL PRODUCTION ABOUT 80 PER CENT

Production of steel in August, in terms of ingots, was probably between 75 and 80 per cent of capacity, but even with various curtailments due to strikes, particularly of railroad shopmen, the average percentage of capacity that was in operation was well above 80 per cent. The productive units in employment did not yield their normal tonnages, partly on account of the weather and partly on account of labor efficiency being well below par at many if not at all plants.

As some men are to be loved for the enemies they have made, the demand for iron and steel must be admired through its being as it is when the basis of demand is lacking in so many respects. It is remarkable that the industry can produce at more than 75 per cent of capacity when there is such a small quantity of steel passing into large construction jobs and when practically no steel at all is passing to the railroads. Just before the war ended the common appraisal was that since steel productive capacity had increased by 40 per cent since 1914 it would require the fullest co-operation of all lines of steel consumption, combined with a very large export demand, to produce requirements that would represent the productive capacity. The buyers absent from the market represent much more than the amount by which production falls short of capacity.

The Chemical Market

New York, August 26, 1919.

The usual seasonal lull has settled on the local market. Quiet is the word which characterizes conditions in vegetable oil, wax and naval stores circles. Dealers in the first two commodities, particularly, are taking it easy until September has run its length and active interest is once more resumed. In contrast, trading in heavy chemicals is fairly brisk, although not so satisfactory as two weeks ago, while business in coal-tar products was never better.

Export business is practically at a standstill, owing to the unfortunate status of foreign exchange. Quantities of merchandise are stored in New York undelivered because sellers would rather hold their goods than execute orders and suffer the heavy losses resulting from the disparity in exchange values.

HEAVY CHEMICALS

Interest in *sodium bichromate* has abated somewhat, bringing a slight reduction in price. The quotation at this writing ranges from 14c-15c. per lb., while 15c-16c. was a fair price two weeks ago. England, France, Denmark and Spain have been the foreign buyers of this product.

Potassium chlorate is receiving few sales at 18c-19c. per lb. Recent arrivals of *Alsatian pyrites*, together with the rumor that Germany is soon to send a like shipment, has contributed to this slackness.

Since the last review a fairly strong demand for *bleaching powder* (calcium hypochlorite) has developed, with South America the leading buyer, although domestic textile mills have bought in fair volume.

That *glacial acetic acid* has been in strong request for South America, England and France, as well as for domestic use, is attested to by the fact that delivery on this acid is not to be obtained under three or four weeks at August 15 quotations.

Muriatic (hydrochloric) is the only other acid offering particular interest. Heavy demand from Cuban sugar interests with a large domestic call has led to the boosting of the price in some quarters from \$1-\$1.50 per cwt. to \$1.75-\$2 for carlot quantities.

Although there is some talk of raising the export price on *caustic soda*, which was placed at \$3.50 per cwt. f.a.s. less 5 per cent by the U. S. Alkali Export Association, offerings are still being made of \$3.30-\$3.40 per cwt. f.a.s.

Alcohol is one of the few items which has increased in market value in the past two weeks. The large quantities of ethyl alcohol being exported, the high cost of wood alcohol and a general scarcity of goods are the reasons advanced for the increase. Methyl (wood, 95 per cent pure) is quoted at \$1.30 per gal. in carlots, an advance of 10c.; pure methyl at \$1.60; denatured, 188 proof, at 52c., and 190 proof at 46c.-48c. per gal.

COAL TAR PRODUCTS

The entire line is booming. During last week, in particular, a heavy volume of business was transacted, the buying coming not alone from dyestuffs and textile manufacturers, but from all classes of trade, such as rubber, paint and polish manufacturers.

Demand is strongest for aniline oil, salicylic acid, aniline salts, dimethylaniline and paranitraniline, the first two being very scarce.

In the words of one manufacturer, "Consumers are begging for aniline oil, but everyone has sold out his supply, as he has that of salicylic acid."

Along with the more refined coal tar products, *crudes* are participating in the increased activity, with toluol and benzol making their importance felt by an increase in price. The new price of benzol, pure waterwhite, is 25c. per gal. in carlots, the less carlot price ranging from 26c.-29c.; the 90 per cent variety, 24c. in carlots; whereas 24c., 25c.-28c., and 23c., respectively, were the previous quotations. From 24c. per gal. in tank cars, toluol has jumped to 26c.

OILS

As in almost everything else, the foreign exchange situation has checked foreign business. On the other hand, there seems to be a tendency on the part of dealers to give less attention to export trade. Since November, 1918, a million barrels of vegetable and animal oils (the entire surplus) have been shipped abroad, leaving just sufficient to meet the normal domestic demand. In view of this condition, prices are expected to remain unchanged for some time.

The linseed oil market is in a slightly easier position than it was two weeks ago. Demand is less urgent, with prices holding unchanged at \$2.22 per gal. in carlots.

NAVAL STORES

Having gone as low at \$1.63 per gal. in the last two weeks, spirits of turpentine has returned to \$1.75. Scarcity of spot supplies is bulling the market.

Although rosins have dropped, due to the low rate of exchange and decreased demand, the market during the past few days has stiffened and appears likely to hold firm at the new prices, according to which W.W. is bringing \$24.75-\$25.00 and E \$18.50, in comparison with \$24.75-\$25.50 and \$19-\$19.50, respectively.

Among the flotation oils, the present price on pine oil, steam distilled, varies from the last quotation of 95c. per gal. by 10c.

St. Louis, August 22, 1919.

The strong demand for *nitric acid* has provided the feature of the local heavy chemical market in trading of the last two weeks. Producers are somewhat at a loss to account for the sudden interest in this acid, but believe that manufacturers of nitroglycerine are taking the bulk of their output.

Continued heavy demand for 60 deg. *sulphuric* has resulted in a tax on the capacity of local producers. The price remains around \$12. Despite slackness in local steel manufacture, demand for 66 deg. *sulphuric* is improving, as it is also for the 98 deg. Failure of Kansas City producers to fill some contracts on the 66 deg. has thrown the burden on St. Louis producers. The price still holds at \$18 for carlots.

Demand is strong for *muriatic acid*, although some difficulties are being experienced in shipping. The 18 deg. is still selling at \$22 in tank car lots. *Sodium bisulphate* (niter cake) is in strong demand. As high as \$3 a ton (representing an advance of \$1) has been offered, but little is on the open market.

Nitric acid has broken records for demand in the last month. The activity is laid to the demands of the nitroglycerine manufacturers. The 40 deg. *Baumé* is selling at 10 and 10½c. per lb., 38 deg. at 9c. and 42 deg. at 11c., all unchanged from the last report.

Zinc chloride is slack and quiet. Demand has fallen off but the price is holding at 4c. on the open market, 3½c. on contract.

Zinc oxide is still strong and even bigger business is looked for in the fall by local producers. Prices remain at 8c. to 9c. per lb. in carload lots, and ½c. higher for smaller quantities.

Ammonium chrome alum is in extremely heavy demand. Within the last ninety days the price has gone from 13½c. to 16½c. per lb. All of it is being exported and is being used by foreign tanners.

Chicago, August 25, 1919.

An accurate summing up of trade conditions in Chicago during the past fortnight is contained in the phrase "no change," as compared with the preceding several weeks. There have been no price changes of note, no great activity in any particular line and no export business of unusual scope. This is undoubtedly due to the fact that prices are now on a fairly high level and a feeling that speculators have a hand in boosting the market to its present point, this being particularly the case in vegetable oils. No great activity can be anticipated until there is either a recession in prices or consumers become convinced that prices are on a firm basis. Present buying is based solely on actual current needs.

Heavy Chemicals—No changes of moment in any item are recorded. *Sodium bichromate*, after its rapid rise in July, is holding firm at about 15c. *Red and yellow potassium prussiate* are as yet very hard to get, 70c. and \$1.10, respectively, being asked for the small quantities available. Among the acids, previous quotations hold good. *Nitric* is holding firm at 10½c. for 40 deg. *Baumé*, despite a rather poor demand.

Coal-Tar Products—*Salicylic acid* at 43c. seems high, but the price stays firm. No change is noted in *benzol* or *phenol*, and with demand good the entire line seems to be fixed for some time to come on the existing price basis.

Vegetable Oils—In spite of rapid and violent fluctuations on the grain exchanges, corn oil, under good demand, remains at 21c. for spot delivery. Linseed is still quoted in one to four-barrel lots to consumers at \$2.48, with 25c. off for large quantities. This seems high, but the fact that the entire production of the crushers is absorbed by the trade as rapidly as offered renders any decline unlikely. The Archer-Daniels Co., in its Minneapolis plant, is said to be crushing 10,000 bu. of flax every day.

Flotation Oils, Naval Stores—The steady increase of prices in these lines continues. Turpentine is now \$1.75, 0.933 test pure steam-distilled pine oil \$1.00 to \$1.05 and destructively distilled pine oil 90c. to 95c. The larger dealers report their entire visible supply of oils sold up to Dec. 1, and that they are not only refusing quotations to new customers but are short-filling orders from old ones. The cause of this famine condition is scant production during the past season and heavy export orders. During the recent harbor strike in New Orleans, 35,000 bbl. of pine oil, intended for export, accumulated on the docks in a few days. Such a severe drain on our already short supply can only produce a serious condition.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, AUG 26, 1919

	Carlots	Less Carlots

Zinc cyanide.....	lb. 09 - 11	10 - 13
Zinc dust.....	lb. 03 1/2 - 04	04 - 04 1/2
Zinc oxide, dry American.....	lb. 03 1/2 - 04	04 - 04 1/2
Zinc sulphate.....	lb. 03 1/2 - 04	04 - 04 1/2

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities

Alpha naphthol, crude.....	lb. \$1.00 - \$1.10	\$1.10 - \$1.20
Alpha naphthol, refined.....	lb. 1.40 - 1.50	1.50 - 1.60
Alpha naphthylamine.....	lb. 35 - 50	50 - 55
Aniline oil, drums extra.....	lb. 26 - 30	30 - 35
Aniline salts.....	lb. 28 - 33	33 - 38
Anthracene, 80% in drums (100 lb.).....	lb. 90 - 100	100 - 110
Benzaldehyde (f. c.).....	lb. 1.00 - 1.15	1.15 - 1.25
Benidine, base.....	lb. 1.00 - 1.15	1.15 - 1.25
Benzidine, sulphate.....	lb. 1.00 - 1.15	1.15 - 1.25
Benzoic acid, U. S. P.....	lb. 95 - 100	100 - 110
Benzoate of soda, U. S. P.....	lb. 95 - 100	100 - 110
Benzol, pure, water-white, in drums (100 lb.).....	gal. 25 - 29	29 - 30
Benzol, 90% in drums (100 lb.).....	gal. 24 - 28	28 - 30
Benzyl chloride, tech.....	lb. 25 - 35	35 - 40
Benzyl chloride, tech.....	lb. 25 - 35	35 - 40
Beta naphthol benzoate.....	lb. 3.75 - 4.50	4.50 - 5.00
Beta naphthol, sublimed.....	lb. 75 - 80	80 - 85
Beta naphthylamine.....	lb. 2.25 - 2.35	2.35 - 2.50
Beta naphthylamine, sublimed.....	lb. 2.25 - 2.35	2.35 - 2.50
Cresol, U. S. P., in drums (100 lb.).....	lb. 18 - 25	25 - 30
Creosol, in drums (100 lb.).....	lb. 23 - 25	25 - 30
Creosylic acid, 95-99%, straw color, in drums.....	gal. 85 - 90	90 - 95
Creosylic acid, 95-99%, dark, in drums.....	gal. 80 - 85	85 - 90
Creosylic acid, 50-55%, 6st quality, drums.....	gal. 60 - 65	65 - 70
Dichlorobenzol.....	lb. 07 - 08	08 - 09
Dimethylaniline.....	lb. 50 - 55	55 - 60
Dimethylaniline.....	lb. 50 - 55	55 - 60
Dinitrobenzol.....	lb. 25 - 37	37 - 40
Dinitrochlorobenzol.....	lb. 25 - 30	30 - 35
Dinitronaphthalene.....	lb. 45 - 55	55 - 60
Dinitrophenol.....	lb. 33 - 36	36 - 40
Dinitrotoluenol.....	lb. 38 - 45	45 - 50
Dip oil, 25% tar acids, ear lots, in drums.....	gal. 65 - 75	75 - 80
Diphenylamine.....	lb. 1.25 - 2.25	2.25 - 2.50
H-acid.....	lb. 1.25 - 2.25	2.25 - 2.50
Metaphenylenediamine.....	lb. 1.20 - 1.80	1.80 - 2.00
Monochlorobenzol.....	lb. 15 - 17	17 - 18
Monochlorophenol.....	lb. 1.00 - 1.15	1.15 - 1.25
Naphthalene crushed, in bbls (250 lb.).....	lb. 06 - 08	08 - 09
Naphthalene, flake.....	lb. 06 - 07 1/2	07 1/2 - 08
Naphthalene, balls.....	lb. 08 - 10	10 - 11
Naphthalenic acid, crude.....	lb. 13 - 15	15 - 16
Nitrobenzol.....	lb. 13 - 14	14 - 15
Nitro-naphthalene.....	lb. 35 - 45	45 - 50
Nitro-toluenol.....	lb. 17 - 20	20 - 25
Ortho-amidophenol.....	lb. 4.05 - 4.15	4.15 - 4.25
Ortho-dichlorobenzol.....	lb. 15 - 20	20 - 25
Ortho-nitro-phenol.....	lb. 90 - 100	100 - 110
Ortho-nitro-toluenol.....	lb. 27 - 30	30 - 35
Ortho-toluidine.....	lb. 2.60 - 3.50	3.50 - 4.00
Para-amidophenol, base.....	lb. 2.75 - 3.25	3.25 - 3.50
Para-amidophenol, HCl.....	lb. 06 - 07	07 - 08
Para-dichlorobenzol.....	lb. 1.05 - 1.25	1.25 - 1.50
Para-nitro-toluenol.....	lb. 1.35 - 1.50	1.50 - 1.60
Paraphenylenediamine.....	lb. 2.75 - 4.00	4.00 - 4.50
Paratoluidine.....	lb. 1.50 - 2.15	2.15 - 2.50
Phthalic anhydride.....	lb. 10 - 13	13 - 14
Phenol, U. S. P., drums (dest.) (240 lb.).....	lb. 1.50 - 1.60	1.60 - 1.70
Pyridin.....	gal. 2.50 - 3.75	3.75 - 4.00
Resorcin, technical.....	lb. 6.50 - 7.75	7.75 - 8.00
Resorcin, pure.....	lb. 6.50 - 7.75	7.75 - 8.00
Salicylic acid, tech. in bbls (110 lb.).....	lb. 35 - 40	40 - 45
Salicylic acid, U. S. P.....	lb. 40 - 45	45 - 50
Salol.....	lb. 72 - 75	75 - 80
Solvent naphtha, water-white, in drums (100 gal).....	gal. 19 - 24	24 - 27
Solvent naphtha, crude, in drums (100 gal).....	gal. 19 - 24	24 - 27
Sulphanilic acid, crude.....	lb. 25 - 30	30 - 35

Tollidine,	lb.	\$1.75	—	\$2.50
Tollidine, mixed,	lb.	.45	—	.80
Toluid, in tank cars,	gal.	.26	—	
Toluid, in drums,	gal.	.30	—	
Xylidine, drums, 100 gal.,	lb.	.44	—	.50
Xylol, pure, in drums,	gal.	.37	—	.45
Xylol, pure, in tank cars,	gal.	.35	—	
Xylol, commercial, in drums, 100 gal.,	gal.	.23	—	.27
Xylol, commercial, in tank cars,	gal.	.22	—	

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow,	lb.	\$0.41	—	\$0.45
Beeswax, refined, yellow,	lb.	.48	—	.49
Beeswax, white pure,	lb.	.65	—	.68
Carauaba, No. 1,	lb.	.88	—	.90
Carauaba, No. 2, regular,	lb.	.65	—	.68
Carauaba, No. 3, North Country,	lb.	.95	—	.60
Japan,	lb.	.183	—	.20
Paraffine waxes, crude match wax (white) 105-110 m.p.,	lb.	.06	—	.06
Paraffine waxes, crude, scale 124-126 m.p.,	lb.	.06	—	.06
Paraffine waxes, refined, 118-120 m.p.,	lb.	.07	—	.08
Paraffine waxes, refined, 128-130 m.p.,	lb.	.08	—	.09
Paraffine waxes, refined, 134-135 m.p.,	lb.	.10	—	.10
Paraffine waxes, refined, 135-137 m.p.,	lb.	.12	—	.13
Stearic acid, single pressed,	lb.	.23	—	.26
Stearic acid, double pressed,	lb.	.27	—	.28
Stearic acid, triple pressed,	lb.	.30	—	.33

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on earload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940,	gal.	\$1.05	—	
Pine oil, pure, dest. dist.,	gal.	.85	—	
Pine tar oil, r.f., sp. gr. 1.025-1.035,	gal.	.43	—	
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.,	gal.	.33	—	
Pine tar oil, double ref., sp. gr. 0.965-0.990,	gal.	.65	—	
Pine tar, ref., in tank cars, 1050-1940,	gal.	.10	—	
Turpentine, crude, sp. gr. 0.900-0.970,	gal.	.85	—	
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990,	gal.	.27	—	
Pine wood creosote, ref.,	gal.	.48	—	

Naval Stores

The following prices are f.o.b., New York, for earload lots.

Rosin B-D, bbl.,	220 lb.	\$16.80	—	\$18.25
Rosin F-I,	260 lb.	18.50	—	20.25
Rosin K-N,	260 lb.	24.25	—	25.00
Rosin W. C. W.,	280 lb.	24.50	—	25.00
Wood rosin, bbl.,	280 lb.	17.00	—	18.00
Spirits of turpentine,	gal.	1.75	—	
Wood turpentine, gross, dist.,	gal.	1.55	—	
Wood turpentine, dest. dist.,	gal.	1.55	—	
Pine tar pitch, bbl.,	200 lb.	8.25	—	8.50
Tar, kiln burned, bbl. (500 lb.),	bbl.	12.75	—	13.50
Retort tar, bbl.,	280 lb.	15.50	—	
Rosin oil, first run,	gal.	.86	—	.91
Rosin oil, second run,	gal.	.88	—	.93
Rosin oil, third run,	gal.	.90	—	1.07
Rosin oil, fourth run,	gal.	.93	—	1.10

Solvents

73-76 deg., steel bbls. (85 lb.),	gal.	\$0.33	—	
70-72 deg., steel bbls. (85 lb.),	gal.	.31	—	
70-72 deg., steel bbls. (85 lb.),	gal.	.31	—	
V. M. and P. naphtha, steel bbls. (85 lb.),	gal.	.23	—	

Crude Rubber

Para—Univer fine,	lb.	\$0.54	—	\$0.55
1 primer cover,	lb.	.31	—	
1 primer Encho ball,	lb.	.31	—	.32
Plantation—First latex crepe,	lb.	.44	—	.45
Hubbed smoked sheets,	lb.	.48	—	.49
Brown crepe, thin,	lb.	.23	—	
Amber amok No. 1,	lb.	.40	—	.41

Oils

VEGETABLE

Castor oil, No. 3, in bbls.,	lb.	\$0.19	—	\$0.20
Castor oil, AA, in bbls.,	lb.	.21	—	.22
China wood oil, in bbls.,	lb.	.22	—	.24
Cocconut oil, Ceylon grade, in bbls.,	lb.	.19	—	.20
Cocconut oil, Cochon grade, in bbls.,	lb.	.21	—	.22
Corn oil, crude, in bbls.,	lb.	.24	—	.25
Cottonseed oil, crude (f.o.b. mill),	lb.	.28	—	.29
Cottonseed oil, summer yellow,	lb.	.26	—	.27
Cottonseed oil, winter yellow,	lb.	.27	—	.28
Linseed oil, raw, car lots,	gal.	2.17	—	2.22
Linseed oil, pure, tank cars,	gal.	2.17	—	2.19
Linseed oil, boiled, car lots,	gal.	2.25	—	2.30
Olive oil, commercial,	lb.	.17	—	.18
Palm, Lagoon,	lb.	.17	—	.18
Palm, bright red,	lb.	.164	—	.17
Palm, Niger,	lb.	.164	—	.17
Peanut oil, crude, tank cars (f.o.b. mill),	lb.	.24	—	.27
Peanut oil, refined, in bbls.,	lb.	.29	—	.30
Rapeseed oil, refined in bbls.,	gal.	1.50	—	1.60
Rapeseed oil, in tank cars,	gal.	1.60	—	1.68
Soya bean oil (Manchurian), in bbls., N. Y.,	lb.	.18	—	.20
Soya bean oil, tank cars, f.o.b., Pacific coast,	lb.	.15	—	.17

FISH

Winter pressed Menhaden,	gal.	\$1.28	—	\$1.35
Yellow blanchard Menhaden,	gal.	1.32	—	1.37
White bleached Menhaden,	gal.	1.32	—	1.38
Blown Menhaden,	gal.	1.38	—	1.40

Miscellaneous Materials

All Prices f.o.b., N. Y.

Sarytes, domestic, white, floated,	ton.	\$25.00	—	\$36.00
Sarytes, off color,	ton.	20.00	—	25.00
Blanc fixe, dry,	lb.	.034	—	.044
Blanc fixe, pulp,	ton.	35.00	—	47.50
Chalk,	ton.	.18	—	.8
Chalk, English, extra light,	lb.	.05	—	.07
Chalk, English, light,	lb.	.04	—	.06

Chalk, English, dense,	lb.	\$.04	—	\$.05
China clay (Kaolin), imported, lump,	ton	25.00	—	35.00
China clay (Kaolin), imported, powdered,	ton	30.00	—	60.00
China clay (Kaolin), domestic, lump,	ton	10.00	—	20.00
China clay (Kaolin), domestic, powdered,	ton	25.00	—	40.00
Feldspar,	ton	11.50	—	16.00
Fluorspar, acid grade, lump, f.o.b. mines,	net ton	\$30.00	—	\$35.00
Fluorspar, acid grade, ground, f.o.b. mines,	net ton	35.00	—	45.00
Fuller's earth, domestic, powdered,	ton	30.00	—	40.00
Fuller's earth, imported, powdered,	ton	.03	—	.06
Pumice stone, imported,	lb.	.023	—	
Pumice stone, domestic,	lb.	1.20	—	
Shells, TN,	lb.	.01	—	
Shells, D. C.,	lb.	.01	—	
Shells, V. S.,	lb.	.01	—	
Shells, Diamond L.,	lb.	.01	—	
Shells, orange, fine,	lb.	.01	—	
Shells, orange, superfine,	lb.	1.35	—	
Shells, A. C. garnet,	lb.	.01	—	
Shells, bleached, bone dry,	lb.	1.40	—	
Shells, bleached, fresh ground,	lb.	1.10	—	
Snapstone,	ton	15.00	—	25.00
Talc, domestic,	ton	60.00	—	
Talc, imported,	ton	55.00	—	60.00

Refractories

Following prices are f.o.b. works:

Chrome brick,	net ton	80-90 at Chester, Penn.
Chrome cement,	net ton	45-50 at Chester, Penn.
Clay brick, 1st quality fireclay,	net ton	35-45 at Clearfield, Penn.
Clay brick, 2d quality,	net ton	30-35 at Clearfield, Penn.
Magnesite, dead burned,	net ton	50-55 at Chester, Penn.
Magnesite brick, 9 x 4 1/2 x 2 1/2 in.,	net ton	80-90 at Chester, Penn.
Silica brick,	net ton	41-45 at Mt. Union, Penn.

Ferro-alloys

All prices f.o.b. works.

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.,	net ton	\$200.00	—	\$250.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon,	lb.	.30	—	.40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon,	lb.	.70	—	
Ferro-manganese, 70-80% Mn.,	gross ton	100.00	—	125.00
Stigolite, 16-20% Mn.,	gross ton	35.00	—	50.00
Ferro-molybdenum, per lb. of Mo.,	lb.	1.85	—	2.00
Ferro-silicon, 50%,	gross ton	85.00	—	115.00
Ferro-silicon, 75%,	gross ton	150.00	—	175.00
Ferro-silicon, 10-15%,	gross ton	45.00	—	60.00
Ferro-tungsten, 70-80%, per lb. of contained W.,	lb.	1.30	—	1.60
Ferro-uranium, 35-50%, per lb. of contained U.,	lb.	7.00	—	
Ferro-vanadium, 30-40%, per lb. of contained V.,	lb.	5.50	—	7.00

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr. O ₃ ,	unit	\$0.60	—	
Chrome ore, 48% and over,	unit	.80	—	
Coke, foundry, f.o.b. ovens,	net ton	5.50	—	\$6.00
Coke, furnace, f.o.b. ovens,	net ton	4.00	—	5.00
Petroleum coke, refinery, Atlantic seaboard,	net ton	11.50	—	12.00
Fluorspar, gravel, f.o.b. mines,	net ton	20.00	—	25.00
Manganese ore, 45% Mn and over,	unit	.50	—	.65
Manganese ore, chemical (Mn ₂ O ₃),	gross ton	60.00	—	70.00
Molybdenite, 85% MoS ₂ ,	lb.	.75	—	.85
Tungsten, Scheelite, 60% WO ₃ and over per unit of WO ₃ ,	unit	9.00	—	12.00
Tungsten, Wulfenite, 60% WO ₃ and over, per unit of WO ₃ ,	unit	7.00	—	10.00
Uranium oxide, 96%,	lb.	.01	—	
Vanadium pentoxide, 99%,	lb.	6.00	—	
Pyrites, foreign, lump,	unit	.15	—	
Pyrites, foreign, fine,	unit	.14	—	.17
Pyrites, domestic, fine,	unit	.14	—	.17
Ilmenite, 52% TiO ₂ , f.o.b. N. Y.,	net ton	38.15	—	
Rutile, 95% TiO ₂ , f.o.b. N. Y.,	net ton	20.00	—	
Chromite, minimum 28% Cr ₂ O ₃ per lb. of U ₂ O ₃ ,	net ton	2.75	—	3.00
Zircon, washed, iron free, f.o.b. N. Y.,	net ton	125.00	—	
Monazite, per unit of ThO ₂ , f.o.b. N. Y.,	unit	42.00	—	

Plant Materials and Supplies

In earload lots, New York, unless otherwise stated

PORTLAND CEMENT, MILL, PITTSBURGH				
Portland cement, at dock, without bags,	bbl.	\$2.30	—	
Lump lime, common, including cartage,	300 bbl.	2.65	—	
Common brick, at dock,	M.	15.00	—	
Yellow pine, 3x4 to 8x8, 20-24 ft. long, at Chicago,	M.	30.50	—	
Yellow pine, 3x4 to 8x8, 20-24 ft. long at St. Louis,	M.	37.00	—	
Roofing, tar pitch (in 400 lb. bags),	ton	60.00	—	
Roofing, asphalt pitch,	ton	21.00	—	
Roofing, asphalt felt,	ton	34.00	—	
Roofing, slate-surfaced, per roll of 108 sq. ft.,	ton	63.00	—	
Roofing, slate-finished shingles, 100 sq. ft.,	ton	5.00	—	
Linseed oil, raw in barrels,	gal	2.25	—	
Linseed oil, 5 gal. cans,	gal.	2.40	—	
Red lead, dry, 100 lb. keg,	lb.	.14	—	
Red lead, in oil, 100 lb. keg,	lb.	.15	—	
Red lead, dry, 5 lb. cans,	lb.	.15	—	
Red lead, in oil, 5 lb. cans,	lb.	.16	—	
White lead, dry and in oil, 100 lb. keg,	lb.	.13	—	
White lead, dry and in oil, 25 and 50 lb. kegs,	lb.	.13	—	
White lead, dry and in oil, 5 lb. cans,	lb.	.15	—	

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.,	100 lb.	\$2.45	—	
Angles, 3 to 6-in., 1-in. thick,	100 lb.	2.45	—	
Tees, 3-in. and larger,	100 lb.	2.45	—	
Plates,	100 lb.	2.66	—	
Rivets, structural, 1-in. and larger,	100 lb.	4.20	—	
Rivets, conehead for boilers, 1-in. and larger,	100 lb.	4.30	—	
Sheets, No. 28 black,	100 lb.	4.35	—	
Sheets, No. 10 blue annealed,	100 lb.	5.10	—	
Sheets, No. 28 galvanized,	100 lb.	5.70	—	

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gauge; 25c. for 19 to 24 gauge; for galvanized corrugated sheets, add 15c., all gauges.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

WARREN—The Phelps Dodge Corporation, Douglas, plans to build a concentration plant at copper mines. H. K. Burch, c/o owner, engineer.

California

HUNTINGTON PARK—The Southern California Iron & Steel Co., 417 Mateo St., Los Angeles, plans to build an iron and steel fabricating plant consisting of about 8 buildings to include an open-hearth mill, hot, rivet, forge and machine shop and galvanizing building, etc. Estimated cost, \$1,750,000.

PITTSBURGH—The Columbia Steel Co., 503 Market St., San Francisco, will erect a steel and corrugated iron rolling plant. Estimated cost, \$250,000. Work will be done by day labor.

TORRANCE—The Torrance Window Glass Co. plans to rebuild the glass factory, consisting of several frame, galvanized iron and brick buildings which were recently destroyed by fire. Estimated cost, \$25,000.

Connecticut

BRIDGEPORT—The Bridgeport Brass Co., Grand St., soon lets contract for the construction of a 1-story, 150 x 236-ft. addition to its casting shop. Estimated cost, \$150,000. The H. M. Lane Co., 701 Owen Bldg., Detroit, Mich., engineer.

GLENBROOK—C. A. Phillips Chemical Co. has awarded the contract for the construction of a 2-story factory, to Thompson & Bauer, 233 Madison Ave., New York City. Estimated cost, \$55,000.

MYSTIC—The Packer Tat Soap Co., Lincoln Ave., plans to build additions to plant, to include a 1-story storage building, 1-story factory and a 25 x 30-ft. power house. Estimated cost, \$40,000. Blidnerbeck & Langdon, Inc., Barrows Bldg., New London, engineer.

WINDSOR LOCKS—C. H. Dexter & Son, Inc., will soon award the contract for the construction of a 5-story, 55 x 100-ft. paper mill addition. Estimated cost, \$100,000. Greenwood & Noerr, 847 Main St., Hartford, engineer.

Delaware

NEWARK—The Continental Fibre Co. has awarded the contract for the construction of a 2-story, 60 x 240-ft. factory to the Austin Co., Bulletin Bldg., Philadelphia. Estimated cost, \$56,000.

YORK LYNN—The National Fibre Insulation Co. has awarded the contract for the construction of a 2-story, 60 x 140-ft. factory, to the Austin Co., Bulletin Bldg., Philadelphia. Estimated cost, \$40,000.

Idaho

CEUR D'ALENE—The Home Builder Mine & Milling Co. plans to build the first unit of nitrate plant on the shore of the Ceur d'Alene Lake. Estimated cost, \$50,000. W. C. Brower, Spokane, Wash., metallurgical chemist.

LEONA—The Idaho Lead & Copper Co., 307 Eagle Block, Spokane, Wash., plans to build 1600 ft. of underground workings and will install a 50-ton mill and compressor. Estimated cost, \$40,000. E. J. Merin, president.

Illinois

SALEM—The city has awarded the contract for the construction of a reinforced concrete, brick and steel water filtration plant here, to W. C. Johnson Construction Co., South High St., Belleville. Total estimated cost, \$12,000.

Iowa

CLARINDA—The city has awarded the contract for the installation of 2,500,000

gal. rapid sand filters, to the Pittsburg Filter Manufacturing Co., c/o E. W. Buchrach, Western manager, 429 Riado Bldg., Kansas City, Mo. Estimated cost, \$11,000.

CORNING—The city will soon award the contract for sewer improvement and a disposal plant. Estimated cost, \$40,000. Archer & Stevens, 609 New England Bldg., Kansas City, Mo., engineer.

DEXTER—The city plans to build a sewer system and sewage disposal plant involving 1030 cu yd. filter sand and 82 cu yd. of filter gravel. H. H. Hough, city clerk.

WINWOOD—The city will soon award the contract for the construction of a complete sewer system and sewage disposal plant. C. H. Currie, Webster City, engineer.

POCAHONTAS—The city will soon award the contract for the construction of a complete sewer system and sewage disposal plant. C. H. Currie, Webster City, engineer. Noted June 1.

Kansas

BLUE MOUND—The Vinegar Hill Zinc Co., Baxter Springs, plans to install a flotation machine, and is changing entire mill from gas to electric power at its Barr mine here. Is in market for motors and transformers. J. G. Trewartha, superintendent.

TRECE—Waugh & Jones Co., Baxter Springs, has recently taken over the old Be Armand mill and plans to enlarge table room and change from steam to gas power. Is in the market for 5 tables, 1 set rolls and 2 gas engines. W. Waugh, manager.

WICHITA—The Sinclair Refining Co. plans to construct an oil distributing plant, to consist of several buildings. Estimated cost, \$150,000. C. W. Birdsall, c/o owner, architect.

Maryland

BALTIMORE—Sherwood Bros., Bank and 8th Sts., plans to construct a 2-story, 75 x 200-ft. oil refinery and warehouse. Estimated cost, \$100,000.

HAGERSTOWN—The Green Mining Co., 7 East Washington St., plans development green stone quarry near here and will install 100-ton daily capacity mill. A. Ludwig, manager.

Massachusetts

EAST SPRINGFIELD—The Atlantic Refining Co., 503 Trucks Head Bldg., Providence, R. I., has awarded the contract for the construction of a 2-story oil plant on Page Blvd. and Robbins Rd., to Metzger & Fisher Co., Otis Bldg., Philadelphia. Estimated cost, \$50,000.

Michigan

DETROIT—The Detroit Soluble Oil Co., Beard St. and Michigan Central Railroad, has purchased site on Dix Ave. and plans to erect a factory for cutting oil there. Architect not selected.

HIGHLAND PARK (Detroit P. O.)—The Maxwell Motor Co., Oakland Ave., will receive bids until Sept. 7 for the construction of a 1-story, 315 x 557-ft. pressed steel plant at Oakland and Massachusetts Aves. Stampings consisting of presses, rolls and furnishing tanks will be installed. Smith, Hinckman & Gravis, Washington Ave., Detroit, architects.

ROYAL OAK (Vinsetta Park Subdivision)—M. L. Brown & Son, engineer, 521 Chamber of Commerce Bldg., Detroit, will receive bids for furnishing labor and material for complete sewer system and disposal works, to include an 8 x 10-ft. vertical creek, 1000 tank, ejector station and sprinkling filter system, for the Vinsetta Land Co. Estimated cost, \$25,000.

Minnesota

ST. PAUL—The St. Paul Welding Co., 173 West 3rd St., is having plans prepared for the construction of a 2-story, 38 x 75-ft. welding shop. Estimated cost, \$115,000. M. A. Wright, Pittsburgh Bldg., St. Paul, architect.

Missouri

HOLDEN—The city has awarded the contract for the construction of a sanitary sewer system and disposal plant, to J. C. Leavenworth, Kan. Estimated cost, \$57,000.

LIBERTY—The William Jewell College plans to construct a new college to include a science department. Laboratory equipment will be installed in same. Estimated cost, \$200,000.

MARYVILLE—The city is receiving bids for the construction of 2 reservoirs, reinforced coagulating plant, etc. Estimated cost, \$15,000. E. Harper, 2408 East 30th St., Kansas City, engineer.

MARYSVILLE—A. D. Hewitt, city clerk, will soon receive bids for the construction of a water filtration plant. Estimated cost, \$50,000.

MILAN—The city has awarded the contract for the construction of a sanitary sewer, including disposal plant, to J. O'Neil, Leavenworth, Kan. Estimated cost, \$29,000. Noted Aug. 15.

ST. LOUIS—The Mississippi Valley Iron Co., 6500 South Broadway, has awarded the contract for the construction of a 1-story, 23 x 32-ft. engine house, and a 36 x 93-ft. gas producing factory, to the Fruin-Conlon Construction Co., Merchants Laclede Bldg. Estimated cost, \$25,000.

ST. LOUIS—The Parker Russell Mining & Manufacturing Co., Laclede Gas Bldg., has awarded the contract for the construction of a 2-story, 98 x 123-ft. silica factory, to C. Stoll's Co., Industrial Bldg. Estimated cost, \$20,000. Noted May 15.

Montana

SCOREY—The city council has awarded the contract for the construction of a sewer system, to include manholes, settling tank and sewage beds, to G. W. Kemper, Minot, N. Dak. Estimated cost, \$45,455. Noted Aug. 15.

LIBBY—The Lukens Hazel Mining Co. plans to build a 200-ton concentration plant and to increase power plant and develop 600-hp. system and installing pipe line from Granite Creek to Lukens Hazel Mine. Also plans to install compressor, jig, table and flotation machines. Estimated cost, \$240,000. Oscar Nordquist, superintendent.

New Jersey

NEWARK—The American Platinum Works, New Jersey Railroad Ave., has awarded the contract for the construction of a 3-story, 50 x 130-ft. reinforced concrete building, to Fred Kilgus, Inc., 13 Sixth St. Estimated cost, \$100,000.

ORANGE—The Board of Freeholders of Essex County, Newark, received low bid for the construction of a sewer disposal plant for sanatorium in Orange Mts. from Averill Mahon Construction Co., 31 Clinton St., \$90,000.

New York

ALBANY—Charles F. Rattigan, superintendent of prisons, will receive bids Sept. 4 for the construction of a concrete dam, cast iron pipe line and mechanical gravity filter plant at Wingdale Prison, Wingdale, N. Y.

BROOKLYN—The E. A. Laboratory, Inc., 80 Broadway, has awarded the contract for the construction of a 2-story, 100 x 160-ft. factory at Spencer St. and Myrtle Ave., to Barney Ahlers Construction Co., 116 West 40th St., New York City. Estimated cost, \$95,000. B. Driesler, 153 Remsen St., architect.

MIDDLETOWN—The Middletown State Homeopathic Hospital Commission received bids Aug. 20 for furnishing all labor and material complete for the construction work of a mortuary and a building from Giles Construction Co., \$21,062, and A. E. Stephens Co., Springfield, Mass., \$28,500.

North Carolina

RUTHERFORDTON—The city has awarded the contract for the construction of a water filtration plant in connection with the proposed waterworks system, to the Norwood Engineering Co., Rutherfordton.

STATESVILLE—The city will receive bids Sept. 16 for the construction of a concrete filter plant, 1,000,000-gal. capacity. Former bids were rejected. R. L. Greenlee, Raleigh, engineer.

Ohio

CLEVELAND—The Cuyahoga Galvanizing Co., 1280 East 59th St., has awarded the contract for the construction of a 1-

story, 60 x 100-ft. factory on 3352 Payne Ave., to G. R. Atkin, 9212 Hough Ave. Estimated cost, \$10,000. Noted Aug. 15.

CLEVELAND—The Enamel Products Co., 341 Eddy Rd., plans to build a 2-story, 180 x 40-ft. addition to factory. Estimated cost, \$10,000.

CLEVELAND—The Standard Brass & Foundry Co., 900 East 97th St., is receiving bids for the construction of a 2-story, 38 x 59-ft. office building and shop. Estimated cost, \$10,000.

CLEVELAND—The Ohio Carbon Co., 3522 Lorain Ave., has awarded the contract for the construction of a 1-story, 51 x 100-ft. factory on 8219 Almiria Ave., to Uhl & Jasper Co., 1900 Euclid Ave. Estimated cost, \$15,000.

COLUMBUS—The Tinker Roller Bearing Co., Duerber Ave., Canton, has awarded the contract for the construction of a 1-story, 282 x 482-ft. factory, at 6th and Cleveland Aves., to D. W. McGrath, New First National Bldg. Estimated cost, \$550,000.

DOVER—The Tuscora Rubber Co. is receiving bids for the construction of a 3-story, 200 x 300-ft. rubber factory here. Estimated cost, \$300,000. W. C. Owen Co., 1900 Euclid Ave., architect.

Oklahoma

COLINSVILLE—The city plans election Sept. 3 to vote on \$40,000 bond issue for the construction of a water purification plant—filters, settling basins, etc. Johnson & Benbow, Firestone Bldg., Kansas City, Mo., engineer.

ENID—The city voted \$500,000 bonds for improving water system, extending sewers and building disposal plant. Black & Veatch, Interstate Bldg., Kansas City, Mo., engineer. Noted July 1.

IDABEL—The city has awarded the contract for the construction of sanitary sewers and sewage disposal plant, to include 2 in-hoff tanks with contact beds and filters, to the Empire Construction Co., Kansas City, Mo. Estimated cost, \$119,800. Noted Aug. 1.

SUNNYSIDE (McLeod P. O.)—The West Virginia Mining Co., Baxter Springs, Kan., plans to construct a 1-story, 100 x 100-ft. market for entire equipment for same. J. Hutton, superintendent.

Oregon

BEND—The Oregon Nitrate Co. plans to develop Stinking Lake and Sheep Mountain nitrate deposits by installing crystallization evaporation system and crushing plant. Estimated cost, \$25,000. J. H. Morgan, Bend, president.

SUMMER LAKE—J. Moore plans to erect a 1-story soda ash and potash plant here, capacity 10,000 tons. Estimated cost, \$190,000.

Pennsylvania

MORRISVILLE—The city plans to build a sewage system and disposal plant. Estimated cost, \$265,000. T. E. Bove, East Rutherford, N. J., engineer.

PHILADELPHIA—The General Manufacturing Co., Delaware and Bigler Aves., has awarded the contract for the construction of a 3-story, 100 x 300-ft. factory and storage building, to H. P. Friend, Inc., Arcade Bldg., Boyer St., Norristown.

Texas

SAN ANTONIO—The Bear Rubber Mills, Ltd., plans to construct a 1-story, 300 x 360-ft. factory on Frisco Rd. Estimated cost, \$200,000. Gulick, Hoff & Ries, 300 Frost Bldg., engineers.

Virginia

BERRYVILLE—The town is having plans prepared for the construction of a new water filtration plant by Gannett, Seelye & Fleming, Harrisburg, Pa., engineers.

ORANGE—The town voted \$70,000 bonds for improving waterworks system, including filter plant, pumping equipment and force main. A. H. Arlow, mayor.

SUFFOLK—The Eastern Oil Co. plans to build plant for the manufacture of cottonseed and peanut oils, daily capacity 75,000 tons. Estimated cost, \$125,000.

Wisconsin

BEAVER DAM—The Malleable Iron Range Co. has awarded the contract for the construction of a 2-story foundry addition, including an annealing department, to the Hutter Construction Co., Fond du Lac. About \$30,000.

CUBA CITY—The Connecting Link Manufacturing Co. plans to erect two big mills and install machinery assembled last fall in the zinc and lead mine 4½ miles northeast of here. Estimated cost, \$24,000. Theodore Waech, superintendent.

JANESVILLE—The Samson Tractor Co., Division of the General Motors Corporation, 88 East Congress St., Detroit, Mich., is building a plant to include a gray iron foundry, core room, sand storage building and pattern shop, to cover an area of 330 x 530 ft. Estimated cost, \$1,000,000. Frank P. Chase, Inc., 645 North Michigan Ave., Chicago.

KOHLER—The Kohler Co., c/o W. J. Kohler, will soon award the contract for the construction of a 4-story, 180 x 260-ft. enamel ware factory, on Elm St. Estimated cost, \$40,000. Brust & Phillip, Free Press Bldg., Milwaukee, architect.

LIVEN—Piquette & Alenber, Plattville, plan to erect a mill and install machinery in the zinc mine here. Estimated cost, \$10,000. J. Piquette, superintendent.

PESHIGO—The Peshtigo Pulp & Paper Co., address J. A. Kittie, president, has awarded the contract for the construction of a 1-story, 70 x 242-ft. paper mill on Main St., to the Jorgenson Construction Co., Main St., Peshigo. Estimated cost, \$60,000. Noted Aug. 1.

SCHULSBURY—The Local Co. plans to erect a mill and install a gasoline or oil engine and jigs in the zinc and lead mine three miles northwest of here. Estimated cost, \$7,000-\$8,000. R. F. Fox, superintendent.

TAYCHEEDAH—The State Engineer's office, Capitol, Madison, will receive bids until Sept. 5 for the construction of 10-in. sewer, 1 sewage disposal plant, consisting of tanks and filters, 262 linear feet of 5 x 6 ft. in tunnel for the Industrial Home for Women here.

Ontario

BOSTON CREEK—The Patricia Mining Co. plans to erect a mining plant and refinery and is in the market for all equipment.

LONDON—C. S. Hyman & Co., Richmond St., has awarded the contract for the construction of a 3-story, 80 x 100-ft. addition to tannery, to P. H. Leonard & Son, Nelson St., Bradford. Estimated cost, \$300,000. Noted Aug. 15.

Manufacturers' Catalogs

THE WELLMAN-SEEVER-MORGAN Co., Cleveland, Ohio, has issued Bull. No. 22, dated June 1, 1913, which contains charts giving the relations in any shaft between power, shaft diameter, torsional stress and speed.

TATE-JONES & Co., Pittsburgh, Pa., has published several booklets: Bull. No. 158 deals with fuel oil burners for furnaces; Bull. No. 157 treats of fuel oil burners for boilers; Circular No. 129 describes fuel oil burning equipment for open-hearth furnaces. Fuel Oil and Its Use" is the title of another new booklet gotten out by this company.

THE SPRAY ENGINEERING Co., Boston, Mass., is distributing Bull. 257 on "Spraco Air Washing and Cooling Equipment," turbine is especially applicable for steam turbine generators.

HOLZ & Co., INC., New York City, announces Bull. No. 4 on "A Machine for Determining the Resistance of Metals and Alloys with Abrasion (Wear)," which describes the Universal Type for tests on rolling or sliding surfaces, dry or lubricated, under variable speeds and pressures.

Coming Meetings and Events

THE AMERICAN CERAMIC SOCIETY will hold its meeting in Chicago, Sept. 24.

THE AMERICAN CHEMICAL SOCIETY will hold its Fall meeting in Philadelphia, Pa., Sept. 2 to 6 inclusive.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its Fall meeting in Chicago, Sept. 23 to 25 inclusive.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its 1913 convention in Philadelphia, Sept. 29 to Oct. 4.

THE AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition of gas appliances and apparatus at the Hotel Pennsylvania, New York, Oct. 13 to 18.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its Fall meeting in Chicago, Ill., Sept. 25 to 27.

THE AMERICAN PEAT SOCIETY will hold its thirteenth annual meeting at Minneapolis, Minn., Sept. 22 to 24 inclusive.

THE AMERICAN STEEL TREATERS' SOCIETY will hold its first annual convention in Chicago, Ill., Sept. 24 to 27.

THE FIFTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in Chicago, Ill., Sept. 22 to 27 inclusive.

THE ILLINOIS MANUFACTURERS' ASSOCIATION will hold a National Conference on "Our Country First" in Chicago, Sept. 8 and 9.

THE INSTITUTE OF METALS DIVISION OF THE A. I. M. E. will hold its next meeting in Philadelphia, Pa., Sept. 29 to Oct. 4.

THE NATIONAL SAFETY COUNCIL will hold its Eighth Annual Safety Congress in Cleveland, Oct. 1 to 4.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its Fall meeting in Chicago from Sept. 24 to 27.

Chicago—Host to Science and Engineering

CITIES, like individuals, have character. Like individuals, also, they may be born with it, acquire it or have it thrust upon them. Furthermore, they have the blessed privilege of changing their characters if, perchance, they have been unfortunate in their first efforts at character building. Mention any great or prominent city, and instantly, if you are familiar with it, its leading characteristic flashes across your mind. Thus, to us, Chicago typifies Industry, and it is as a great industrial center that we think of her in the last week of this month, when she becomes host to scientists and engineers whose work forms the foundation for many of the industries in her vicinity. We can easily forget her appellation of the Windy City; we can pass by her vaunting "I Will" and substitute therefor a more appropriate "I Do"; and we can even forget such an occasional misfortune as an alleged pro-German mayor; but we cannot wholly obliterate our recollection of the hum of genuine industry that vibrates in her atmosphere, nor forget the mental impression that a tremendous production of the country's needs comes from within her confines or adjacent communities. Chicago typifies Industry.

It will tax even a great industrial, not to say industrious city, however, to give adequate attention to a large exposition and five conventions in the same week. We recall no other instance of such a conjunction in the history of scientific and engineering societies, and in some respects we hope that it will not recur in the near future. Good and impressive as it may be, it nevertheless taxes the ability of many who are interested in two or more of the events which are scheduled for simultaneous occurrence; and it leaves one with a sense of indigestion, if indeed the prospect of so plenteous a program does not dull the edge of appetite and lessen the pleasure of anticipation.

The complete program for the week of September 22 appears elsewhere in this issue. The central figure is the Fifth National Exposition of Chemical Industries, in conjunction with which will be held the regular meetings of the American Institute of Mining & Metallurgical Engineers, the American Electrochemical Society, the American Ceramic Society, the Technical Association of the Pulp & Paper Industry, and the American Steel Treaters' Society. The last named society, in addition to its meeting, will hold a special exhibition of heat-treating appliances and heat-treated products at the Seventh Regiment Armory. The Chemical Exposition will be held at the Coliseum and First Regiment Armory, and the meetings of some of the societies

will be held there also. Details are given elsewhere in this issue.

The four North Central States, of which Chicago is practically the geographical center, are the subject of considerable attention in this issue of CHEMICAL & METALLURGICAL ENGINEERING. Already a great industrial region, we believe that it is destined to increase in importance and power, and assume a larger place in the scheme of national economy. Centrally located and having unexcelled rail and waterways, the factors are all present for utilizing in the highest degree the natural resources of the region in the shape of minerals and cheap power. Intelligent labor is plentiful, education is at hand in many forms, the spirit of scientific research is exemplified in State and national laboratories and institutions, and there is plenty of opportunity for professional intercourse among men similarly minded. It is with the purpose of familiarizing our readers with this important region that we publish symposia on the industries and resources of Illinois, Indiana, Michigan and Wisconsin. Those visiting Chicago during the week of September 22 will have an opportunity to make short excursions into the adjacent territory with the scientific and engineering societies, and thus visualize more clearly the conditions which we have tried to portray by word and illustration.

American Chemists In Peace Session

THE fifty-eighth meeting of the American Chemical Society at Philadelphia may be recorded as a distinguished and important event. Not only were the papers timely, but there were general features which could not remain unobserved by any thoughtful chemist who attended the convention. Of the general features we think the most noteworthy was the spirit of resolution that dominated the meeting. In April at Buffalo many members were still in uniform and had hardly returned to their normal work. Industrial chemistry seemed still to be on the springboard, swinging their arms. Now they have jumped in and are swimming. There was no professional boasting. Everybody knows that the waters are deep and the goal distant; but the men are resolute.

Another note was the greater sense of the dignity and the public responsibilities of the profession. It is said of Professor TYNDALL that he had a faithful Scotch servant who rapped at his door every morning, uttering aloud the message with an unctious Scotch burr: "Ar-r-rise, sir! Ar-r-rise! 'Tis 7 o'clock and ye have a g-r-reat wor-r-rk to do this day!" One could almost imagine that the ghost of the old Scotchman had been

passing before the doors of American chemists, declaring his message.

Too much praise can hardly be accorded to President NICHOLS and his able collaborators among the directors and the advisory committee, and to the Philadelphia and Delaware Sections for the completeness of the arrangements. The value of a man of inspiration at the head is sure to be reflected all along the line, but the earnestness and seriousness of the meeting extended far beyond any single man or group of men. A ringing note, however, was struck by the president in his call to organized labor, in response to the resolutions of the American Federation, to join with the Society in bringing about that quality of use and understanding of science which it demands. It was a hearty and honest call, made with the welfare of all in view.

Repeated again and again was the demand that chemists be men of broad and abundant culture. The reasons given for this are twofold: that in research a trained and active imagination is required, and in industry, it is the chemist who represents to all the men employed the scholastic and philosophical elements of manufacture. Here indeed, as one of the speakers at the banquet emphasized, the man of culture is most needed. Many of the men who work with their hands have not trodden along the delectable paths of life. Many feel that they have not had a fair chance, and many indeed are right; they have been unfortunate in their surroundings. It is here that the chemist who, being proficient in the greatest of the arts, which is the art of living, may function to that betterment of this war-weary and distressed world which is the heart's desire of all good men.

The Potentiality of A Glucinum Industry

IN 1902 Mr. J. H. L. VOGT stated in the *Transactions* of the American Institute of Mining Engineers, vol. 31, p. 128, that between 0.01 and 0.001 per cent of the entire earth's crust is glucinum. In DANA's classical "System of Mineralogy" the enumeration of localities where various glucinum minerals are found shows that they comprise a large list; while Bulletin No. 624 of the U. S. Geological Survey, on "Useful Minerals in the United States," shows that we have a relatively large quantity of glucinum minerals in our own country. In addition to this information regarding the occurrence of glucinum and its minerals, we have available many experimental data on the production and on the valuable properties, *sui generis*, of the metal, its salts and alloys.

Under these circumstances one might be led to expect that the glucinum industry is already a *fait accompli*, whereas in reality as long ago as June 14, 1916, Dr. J. W. RICHARDS stated in a paper read before the American Institute of Chemical Engineers that "dealers in rare chemicals will charge you, at present, \$300 per ounce for a specimen of it" (glucinum). And in the *Revue de Chimie Industrielle* for June, 1919, we observe the prophecy: "A day will come when its [glucinum's] uses will probably increase considerably. It is only a matter of realizing the economic conditions of production and price."

These facts will prove of interest to those who have at heart the potentialities of new industries. Elsewhere in this issue we publish an extensive compendium of our chemical and metallurgical knowledge of the metal,

covering the subject from the time of the element's discovery up to a very recent date. We hope and believe that it will stimulate interest in the subject and contribute in some degree to the establishment of a glucinum industry in this country.

The Fallacy of Class Distinctions in Chemistry

IN A notice issued some time since by the New Jersey Chemical Society it was recorded that "In order to promote contact of the industrial chemists with teachers of chemistry in the State of New Jersey, the committee on membership announced that those engaged in educational work, both collegiate and preparatory, would be welcome to membership in the Society."

We are glad to learn it. And if it indicates that the founders thought to make the Society a body of technical chemists exclusively, it is evident that they have resolved to correct the error.

We have been very fortunate in this country in keeping men engaged in pure and applied chemistry within the same organizations. The only difference between the two pursuits, as has often been repeated, is that in pure science one selects his own problem and takes his own time over it, while in applied science his problem is given to him and his time is limited.

There is no room for snobbery in either division. Let us imagine a man engaged in pure research who scorns industry as a dancing master scorns rubber boots and who declares himself to have "no interest in anything that is useful"; let us imagine him as soaking in soothing unreasonableness and ignorance of industry and its hot struggles that kill the weak and exalt the strong. How he behaves is a matter of taste, but so long as his work is important he cannot keep his work from counting in industry.

We declare that it is impossible to keep industry away from pure science, provided always industry follows research as it should. Of late we have found the demand growing urgent in properly conducted industrial research laboratories for advanced physical chemists. The time saved and the unnecessary experiments that are avoided by profound scholarship are no less than amazing. It is right here that the chemical philosophy of such savants as THEODORE W. RICHARDS, JULIUS STIEGLITZ and other great teachers comes into play. Abstract studies into the nature of chemical reactions have blazed the trail for many an industrial advance. No man who takes a forward step along the ways of pure science can keep enlightened industry out of his tracks. Such a pioneer does not need a factory number.

As for snobbery on the other side—the belief that because industrial chemists who have passed the stage of hack work are different in any particulars of merit from those who teach because they are better paid—it is absurd. The capacity for administration is an endowment rather than an art to be acquired; and so is teaching. So, too, is the capacity for research. They are gifts, like red hair, and some few of us have the first of these blessings, a few have the second and a few enjoy the third. The vast majority of mankind are better off at other tasks than any of the three mentioned. But the work of each is needed, and all function best when they are in association and live in community. We have seen good time wasted in teaching students of chemical engineering how to operate simple apparatus which they might have learned from a skilled

laborer; the while a course in physics which would have opened their minds to what they needed most was being neglected.

There is every reason why we should avoid class distinction in chemistry. We hope the Princeton and Rutgers faculties and the high school teachers generally will join the New Jersey Society. It will be an excellent thing for the teachers to see the many applications of their subject in everyday doings and things. It will enable them to blow the breath of life into their work and to explain the reason why abstractions that seem to be only "mind-improving" school book agonies are in constant use in daily life. For the chemist in the works whose operations are likely to be circumscribed by the limitations of routine practice, it will be an inspiration to foregather with men who select their own problems and dig into the unknown.

Recognizing the Importance Of Non-Metallic Minerals

A FAVORITE expression of a friend of ours is that "periodically we ought to revise our prejudices." Likewise we ought periodically to extend our vision, revise our classification of essentials and non-essentials, and readjust our concept of the relative importance of things. If prejudices are susceptible of revision, and we may pause to remark that they are, then certainly it is possible occasionally to take stock of our industries and their needs and revise our estimate of the relative importance of, let us say, minerals.

We venture the assertion that there is a wider familiarity with the production, treatment and uses of metallic minerals, such as galena, blende, hematite, chalcopyrite and pyrite, than with such non-metallic minerals as dolomite, talc, feldspar, fuller's earth and gypsum. The reasons are obvious. Minerals of the first class produce the common metals, and have the metallic luster and other physical properties that distinguish them, even for the layman, as something of importance in the earth's crust. The non-metallics, on the other hand, are apt to lack even distinguished appearance, being earthy and unattractive. Furthermore their uses are likely to be less apparent, and consequently they are not regarded as economically important. Not the least factor in drawing attention to the metallics is the amount of research that has been devoted to them by both Government and private agencies. In fact the pendulum of mineral research has been swinging so strongly in the direction of the metallics that we have been in danger of forgetting the importance of the non-metallics.

If the reader is interested in gaining an insight into the importance of the non-metallics in our industrial life, he will read the contribution of Mr. LADOO, published elsewhere in this issue. The non-metallics are the basis of many of our chemical industries; they form the raw materials out of which the finished product is fashioned, or, quite as often, they are used in the form in which they are taken from the earth, requiring no beneficiation or treatment whatsoever. Oftentimes their properties are obscure and the reason for their action poorly understood. This leads to rule-of-thumb application, to empirical use, and often acts as a bar to progress.

The great need of the non-metallic mineral industry in the United States today is systematic research prosecuted with as much intelligence and vigor as has been expended on metallic minerals for the past decade or

more. The Bureau of Mines is an excellent agency to undertake this work as far as its national aspect is concerned. State institutions of learning can supplement the work either in co-operation with Federal authorities or by independent investigations on minerals of importance within their own borders. We believe it is not too optimistic to predict that ten years of research of the kind indicated will place our chemical industry and allied industries on such a footing as will establish them permanently in competition with similar industries in other countries, provided always that we have raw materials of equal quality and quantity.

Mechanical Charging Of Lead Blast-Furnaces

IT IS popularly supposed that it is more difficult to run a lead blast-furnace successfully than one smelting copper or iron ores—at least the operators constantly emphasize the extreme necessity of a most uniform charge column. DWIGHT long ago pointed out that a distinct gradation from fine at the side walls to coarse at the center is a prime essential of good furnace work, but no considerable segregation in sizes or in materials is allowable either vertically or longitudinally, else overfire and serious losses in recovery will ensue. Not that a uniform charge is not extremely desirable on any furnace, for it unquestionably is, but metallurgists believe that a lead furnace will stand less abuse than any other common smelter.

Twenty-five years ago hand-charging was universal practice; ores were bedded by hand, carted and dumped on the furnace floor, there to be shoveled into the furnace top at a total expenditure of perhaps one hour's labor per ton of charge. In its entirety this labor-wasting system is now seldom encountered, although mechanical devices for bedding are even yet rare. The first long step in advance instituted a charge car to be filled with several tons of miscellaneous materials by barrows, then to be hauled to the furnace and dumped into the shaft. In this manner about three tons of charge can be put into a furnace per man-hour. Labor efficiency is again tripled by most modern systems of mechanical assembly and charging.

Arguments against an exclusively mechanical system on the ground that it causes segregation lose weight when coming from men who are using a charge car not only narrower but actually much shorter than the furnace top. This is said with all due regard to the ideas of those who wish the charge car distinctly smaller than the furnace cross-section, so that it can be placed as desired, into this or that corner, side, or end of the furnace, to humor the peculiarities of accretion and charge descent. But are not these abnormalities mostly due to inferior charging? Then why spend good money in getting a correct mixture to the charging floor, and waste it in one fell drop?

Various causes other than inertia have prevented ready adoption of labor-saving devices at lead plants. Differences in general plant arrangements make it impossible to copy widely a successful layout, while variation in furnace top construction requires special design of charge car itself, so that a car very successful on a hooded furnace would be useless on another whose gases were drawn off below the floor or through a thimble. Mechanical handling in general is accompanied by rough handling, which is disastrous to the friable sinter forming such a large proportion of the present

burden. Again, since no device will be perfect, irregular furnace operation will require at times uneven corrective charges; in other words, the system to give uniform charges should be flexible enough to give non-uniform charges when desired to control the furnace action.

Combine all these requisites in a layout which will minimize the cost of plant, operating charges and the handling of materials, and the problem is by no means an easy one. The Dwight-Messiter system so successfully operating in copper smelters has not found much favor in lead plants, principally because the extensive conveyor system involves much handling—that is, many drops—and because certain portions of the charge, such as sinter, flux and coke, do not require bedding, in fact are preferably placed in the furnace in layers. Therefore it seems probable that, for economical construction, sinter can be passed through bins of fair reserve capacity, while limerock, slag, coke, or other materials of uniform analysis can be merely dumped from a trestle, and drawn off into a tunnel below, the toes and ends of the piles remaining as surplus emergency stock.

A series of individual bins have in certain instances been successfully substituted for the time-honored orebeds. They are much more expensive to install, especially if each has a weighing mechanism attached, and they require excessive switching by the charge-collecting car. If but a hundred pounds are drawn off for each charge, a small shipment is quickly exhausted. Orebeds containing a thousand tons of material or more have many points of metallurgical advantage, if only in making for uniformity in furnace operation. Excessive labor is not essential for their assembly; a rectangular tank-like bin covered by a tripper on a low traveling bridge will build as good a bed as can be done by the most skilful laborers.

So much for the storage end. The engineer will next concern himself with getting the material into a charge car in uniform layers. Mechanically this may be done by bringing the charge car to the stock, or *vice versa*, either by rail or conveyor. As before noted, the first mentioned scheme has been installed successfully, but requires much switching and expensive maintenance of a scale car, or if a rugged hopper car is used, will involve many costly weighing devices. By the second plan, if a series of smaller receiving bins are assembled over a single loading track, a minimum of charge-car movement and a very few "weighing-off" conveyor-feeders would do the work. Either arrangement can closely simulate successful hand-filling practice and by regulation of speed of car or ore-stream, "humps" of material can be built up as required by the furnace man for corrective purposes.

To take the best advantage of the close control thus available in the condition of the charge as it arrives at the furnace mouth, it is essential that the burden be placed into the furnace in practically the same condition as it is delivered. That this is only approximated is easily seen from present arrangements. The wheels of the charge car itself may be about two feet above the floor, carried on a transfer, while the shaft may be open eight to ten feet to the bottom of the smoke flue. A six-ton charge dropping sheer ten feet would appear to be disastrous to the stoutest furnace construction—as a matter of fact, the charge runs slowly out of slots in the car, and strikes a deflector on its way down, not only re-

ducing the impact but correcting the segregation inevitable from center charging.

A charge properly assembled should not need distributors or deflectors to get it into a lead blast-furnace correctly. A car with a real quick-opening flat drop-bottom, of the same cross-section as the furnace mouth, should be able to place the charge into the furnace in the same condition as it arrives. The impact of the falling mass would then be a factor of importance and could most readily be reduced by a low-hung car entering a hooded top, with the burden kept as close to the rail as metallurgical circumstances will permit.

Thus would the maximum value of mechanical charging be attained. It is evidently independent of the method of storing the components, of gathering them, or getting them into the charge car. The main thing is to get the materials into the furnace in a pre-determined and controlled manner. At present the deflector controls the situation, but the question is raised, Could not the distribution be more properly done under closer control and at more leisure in a charge car so designed as to dump quickly and without further segregation?

Co-operative Industrial Research Laboratories

EARLY last winter Mr. C. E. MEES, head of the research laboratory of the Eastman Kodak Co., delivered an address in New York on Research Laboratories in Industrial Establishments. He spoke from the vantage of ripe and successful experience. He gave many valuable hints, and pointed out not a few hazards in well-meant laboratory practice. It was an excellent address. Later Mr. P. G. NUTTING, head of the Westinghouse research laboratory at Pittsburgh, presented a paper on Institutes of Applied Science, in which he outlined in considerable detail the qualifications which a research institution should possess to be efficient in "turning out experts and in establishing vital and fundamental principles." He outlined seven principal types of research institutions that are already in existence in this country, and concluded his paper with enumerating the benefits to be gained by a great series of such organizations which should cover over thirty fields of applied science. His sketch of plans for the conduct of such co-operative institutes was illuminating, and in many respects admirable.

Just now, however, we want to emphasize the immediate need of research in industries, the need of it today; in our native clays, for instance; in the cement industry; in pulp and paper; in refractories, despite the work already done, for the prosecution of what VICTOR MEYER called pyrochemistry; and in many other directions. When captains of industry are so minded they can get a first line on what they need in many different ways. The main thing required is intelligence at the source. Industrial establishments must retain a reasonable measure of individuality, and if this is not to be found in standard products it may be looked for in methods. Natural raw materials cannot be economically standardized; we have to take them as they come with varying geologic histories and of diverse chemical composition.

And while our interest is in industries as made up collectively of many plants, we cannot ask the individual manufacturer to consider his own responsibilities lightly, or as merely incidental to the whole. He must

bear his own establishment constantly in mind, if he is of the right sort and wants to keep ahead of the game. The way to do this is by progress rather than by secrecy. Given two plants, one modern and well administered, the other antiquated and operated by rule-of-thumb methods, it takes no gift of prophecy to foretell which will succeed and which fail. It is not secrecy that counts; it is capacity. The great purpose of co-operative research is to keep up the tone of the whole of an industry. This is essential for national reasons, in order to prevent failures and the consequent miseries of unemployment no less than to avoid that general ill-repute into which the incompetent few can bring all engaged in any single line of manufacture. The really able manufacturers are those who see to it that they keep ahead. They acquaint themselves with principles rather than with details of which their competitors are ignorant. They ascertain if any one else is working along their particular lines, whether in universities, private laboratories or endowed institutions. This is not accomplished by spying or underground methods; it is the result of being informed, of speaking the language, of familiarity with the literature—and in large part it is the reward of intelligent curiosity.

In short, the really able manufacturers are men of science, or they are closely associated with such persons of standing. In this wise they become familiar with the philosophy of their various processes. Also they attend meetings which would provide no enlightenment to their unreceptive competitors because the latter class do not grasp the vast complex of relevancies in applied science. The competent always have something on the stocks, in one laboratory or another, if not in their own, and they reap rich harvests accordingly. Old Uncle DANIEL DOLLARDOODLE never could make out how they turn the trick.

The White House Conference on Labor

EARLY next month twoscore or more carefully selected men will gather in Washington at the invitation of the President to seek a solution of the labor problem. Precedent does not encourage one to be hopeful that such a gathering, or any other, can solve the problem. Great questions like this do not usually have an "answer" that is adequate, requiring only search that it may be found. Ten years ago there was the White House conference of Governors, to consider the subject of conservation. The interchange of views undoubtedly did good, but no comprehensive program resulted, because such a program, to be effective, required the active co-operation of a very large number of men, with very divergent interests.

It is quite true that the coming conference could recommend legislation by Congress, but it is extremely doubtful whether any vital legislation that would be recommended would be enacted. Even were Congress disposed to legislate, it would be very difficult to draw up desirable legislation. Suppose, for instance, it should be desired to legislate against strikes, as it is desired to do in the case of the railroads. How could a line be drawn, defining in what industries or at what plants strikes must not occur?

An awkward feature of such a conference is the matter of representation. It is very difficult to find real representatives of unorganized labor, while representatives of organized labor are exponents of a system that

strikes at the very roots of industrial peace. There can be no true co-operation between employers and organized labor, because organized labor refuses to recognize quality.

An illustration will serve to emphasize the vital importance of this fact. There was a time, say 15 or 20 years ago, when the average steel mill produced little steel except ordinary "mild steel," which covered a multitude of characteristics little known and still less regarded, while some of them produced what was broadly known as "rail steel." The buyer had to take what he got. Gradually it developed that there was money in suiting the steel to the special requirements of the consumer. At first the steel mills yielded rather grudgingly to the demands of customers that they be furnished steel a little different, but soon this feeling was supplanted by an active desire to meet the precise requirements of the user. Instead of being content with filling, or attempting to fill, the expressed desires of the buyer, many mills established research departments, resulting in the mill being able voluntarily to offer the customer or prospective customer a steel better adapted to his requirements than the buyer had been able to conceive.

Thus there has been established co-operation between the seller of steel and the buyer of steel, and this co-operation has proved mutually advantageous. More steel is being made and consumed to-day than if this co-operation had not been developed.

The system of organized labor presents no such co-operation. It strives to prevent co-operation. The pay per day is to be so much, no matter what the day's service amounts to. No day's work is worth more than another day's work. It is as if the seller of steel should say: "Here is our steel. If your axle is not strong enough, buy more steel and make your axles larger. If 25 per cent of the sheets break in forming, buy one-third more sheets. That will give the steel mills more work."

What is desirable is the replacement of the system of organized labor by a better system, but in all probability organized labor will contribute the chief spokesmen for labor.

For some time there was a strong outcry against "paternalism" on the part of the United States Government. OTTO H. KAHN delivered a very forceful address on "The Menace of Paternalism" before the convention, at Chicago, of the American Bankers Association, September 27, 1918. The address was reprinted in pamphlet form and was read with interest and approval by a great many thinking men. The "menace" has now almost died out, not chiefly because MR. KAHN spoke against it, but chiefly because practical experience has shown that it won't work.

Paternalism, however, is paternalism, whether it be government paternalism or not, and the fundamentals are such that it is as insufficient if it is the one kind or the other. Now, unfortunately, a large part of the defense of "open shop" employers against unionization is the paternalism these employers practice. What is done may be, and probably is, in itself altogether unobjectionable. It is "good work," so to speak, but it is not co-operation, and it is co-operation that is requisite. Can the coming conference at Washington devise a method whereby there will be co-operation between the employer as an individual and the employee as an individual?

Readers' Views and Comments

War Department Deserts Chemical Warfare Service

To the Editor of Chemical & Metallurgical Engineering

SIR:—The editorial in your issue of Aug. 15, entitled "War Department Deserts Chemical Warfare Service," prompts this letter. As a chemist, I sympathize with your attitude. I believe that such of the recent developments in methods of warfare that are usually described as "chemical warfare" should be the subject of continued study and research. And much of this should be done by chemists and physicists of the best training and widest experience. On the other hand, I do not believe it necessarily need be done by a distinct branch of the Army organization. My experience as a Captain in the Chemical Warfare Service, A. E. F., leads me to believe that the various activities of the Chemical Warfare Service, with perhaps one exception, could be performed satisfactorily by the ordinary departments of the Army. An enumeration of such activities, with their disposition according to my idea, may justify this statement.

The study of gas mask chemicals must be made, of course, by chemists and physicists. But why should not this, as well as the production of the finished masks, which is but a manufacturing proposition after all, be under the jurisdiction of the Ordnance Department? Likewise, why should not the chemical research necessary to the study and development of toxic gases, the engineering research necessary to their manufacture, and their manufacture itself, be functions of the Ordnance Department? Another important activity of the Chemical Warfare Service was the training of gas officers who were to be responsible for the "gas discipline" of the troops. It seems to me that this is a purely military matter that can be handled by regular line officers as part of their regular duties. Certainly scientists are not necessary for this duty. I am assuming, of course, that the professional training of these line officers will be modified so as to make them competent to do this. It will be necessary in this connection for some soldier-chemist to write a text on "Military Gases" of the same general character as Weaver's "Military Explosives."

As the offensive use of gas has become largely an artillery problem, artillerymen can be instructed in the special uses of the various gas shells, as they are at present instructed in the particular uses of shrapnel and high-explosive shell. The offensive use of gas from mortars and projectors and the use of smoke has largely been in the hands of specially trained "gas troops" under the Chemical Warfare Service organization. But in my opinion there is no necessity for such classification; they could very well be called engineers, or even given an infantry classification and organized much as the machine gun units are, in their relation to the rest of the Army.

On the other hand, I believe that there should be on the staff of each division, or certainly of each army corps, a soldier-chemist, whose chemical training must be the very best, and whose chemical judgment must be matured by proper experience, whose duty would be to investigate personally the gas activities of the

enemy in his sector, so as to keep his commanding officer of the War Department advised of gas developments during the campaign. There might even need to be an emergency laboratory available to these officers. But this should be so near the front as really to serve its emergency purpose; much too near the front to serve as a research laboratory. These officers might properly be classified as a chemical service. But their number would be so small that even in this case I believe it would be better to classify them in one of the existing departments.

Thus, it seems to me that the proper activities of the Chemical Warfare Service can be apportioned among the existing departments of the Army. Perhaps it is the plan of the Army to do this very thing, and to abandon merely the Chemical Warfare Service classification, not its activities.

B. B. FREUD,

Associate Professor, Armour Institute of Technology.

Late Captain Chemical Warfare Service, A. E. F.

Experimental-Retort Tests of Orient Coal

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have just returned from my vacation and note that you have published "Experimental-Retort Tests of Orient Coal" in the Aug. 15 issue.

In the absence of Mr. McBride, who is at present away on vacation, I want to call to your attention that you omitted the special acknowledgment we gave Mr. Edwin Barnhart, engineer of tests for the Bethlehem Steel Co., who developed the retort, and Mr. D. H. Duval, assistant chemist, who has conducted the retort tests for the company. We are indebted to them for their valuable assistance rendered at the time the tests were made.

I. V. BRUMBAUGH.

A Rapid Method for the Analysis of Red Lead and Orange Mineral

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the July 15, 1919, issue of CHEMICAL & METALLURGICAL ENGINEERING exception is taken by Mr. Eric John Ericson as to the proper credit for the method used in a paper on "A Rapid Method for the Analysis of Red Lead and Orange Mineral" published in the *Journal of Industrial and Engineering Chemistry*, vol. 8, No. 3, page 237, March, 1916. It is Mr. Ericson's claim that I failed to give him credit for a prior application of the method as used. The method as used in that paper is taken from the third English edition of Treadwell and Hall's *Analytical Chemistry*. Reference was made to that edition so that it would be applicable to the latest publication of that book. If Mr. Ericson would acquaint himself with the literature on this subject, he would find that these reactions are described substantially as given in Treadwell and Hall's first English edition.

The question of the decomposition of PbO , by H_2O , was first discovered by Thenard and was first carefully studied by Brodie in 1850 (Brodie, *Phil. Trans.*, 1850, p. 759; *Chem. Soc. Quart. J.*, IV, p. 194; *Chem. Soc. Quart. J.*, VII, p. 304). As Thenard discovered hydrogen peroxide and studied its properties in 1818, this phase of the matter seems to have been common knowl-

edge for over a century. Brodie's work was a detailed study of the reaction:

This reaction is also mentioned in Watt's Dictionary of Chemistry, published in 1871, vol. 3, page 198.

In Treadwell and Hall's book credit is given to the method of Lux. In so far as the method under discussion deals with the decomposition of red lead by nitric acid, this is fully described by Lux in his paper on the "Gravimetric Determination of Minium," published in 1880, *Zeit. für Anal. Chem.*, 19. The other part of the reaction is described in Treadwell and Hall's book with no reference given, due probably to the fact that this matter was common knowledge for so long a time.

From a study of these references, it will be seen that I was correct in crediting the method as was done. It is to be regretted that anyone making the claims which Mr. Ericson has made would fail to make a thorough

study of the prior work done on this subject. While his method is a most excellent one, he has probably claimed too great originality for himself. In the light of these earlier investigations the mere fact that Mr. Ericson used this method for a dozen years in the zinc industry, and on Joplin ores principally, does not establish the claim that he should be credited with the prior application of this method as it refers to the analysis of red lead and orange mineral.

At the same time, it is indeed strange that he has only made the discovery which he did in respect to the credit he presumes to be due him after more than three years, the original paper being published in March, 1916, while his letter appears in July, 1919. It is apparent he has shown a great disregard of former investigations and publications.

JOHN A. SCHAEFFER,
Chief Chemist

The Eagle Picher Lead Co.,
Joplin, Mo.

Western Chemical and Metallurgical Field

Boulder County Tungsten

READERS interested in tungsten are undoubtedly acquainted with the fact that this specialized branch of metallurgical industry has been marking time for several months, but they may not know that the mines and mills in Boulder County, Colorado, are almost completely abandoned. This region, the most important American tungsten source, shows many after effects of the wild flight of market prices. Fabulous quotations early in 1916 produced a record tonnage by the use of unusual expedients, and when the market settled to a relatively narrow fluctuation during 1917 (around \$24 per unit), a substantial output was forthcoming from the mines and mills developed during the boom. This price remained approximately stationary up to the end of the war, and was affording a good return, as may be surmised when comparing it to a pre-war price of \$6 per unit. Unfortunately, however, when the War Minerals bill was under discussion in Congress, the prediction was freely made that Colorado ferberite would soon be selling for \$30 per unit WO_3 , a prediction never realized, but which caused many of the small leasers and operators to curtail their mining and hold back their concentrates in expectation of the higher price. This somewhat concerted action cut into the 1918 production, and the result was that when the larger producers began shutting down in the fall there was really but a modest amount of spot ferberite in existence.

Thus all the mills in the district are now shut down; the principal ones being the Wolf Tongue Mining Co., at Nederland; Vasco Mining Co. (American Vanadium Co.) at Tungsten; Primos Chemical Co., at Lakewood; Rare Metals Co., at Rollinsville; Tungsten Products Co., at Boulder, and the Red Sign Mill, at Ferberite. Operators, large and small, are waiting for a high tariff to exclude cheap Asiatic ores; meanwhile large quantities of the latter are being imported and will command the market for months to come, tariff or no tariff. However, there is little or no ferberite to be had, and many users require this pure mineral rather than the imported ore, high in tin, manganese and copper. A decided premium is therefore to be expected, which may well grow to a point where mining in the richer Boulder veins will again be possible. As a matter of fact, leased ore is now

being taken from the Black Rose mine at Dry Lake, some 4½ miles from Nederland, and shipped to Denver for magnetic concentration to supply a sizable contract running over the balance of 1919. This may be the forerunner of a revival in ferberite.

Dr. Eckley and some of his associates at the University of Colorado were able to perfect a chemical process for the production of very pure tungstic oxide from impure materials, and their commercial plant (Black Metal Reduction Co.) at the mouth of Boulder Canyon has been in operation for nearly two years. They first bought up mill wastes from their immediate neighborhood, a fine, impure product which could not be cleaned by water concentration. This was subjected to an alkaline fusion, the mass then leached, the filtrate purified and finally WO_3 precipitated pure enough to pass the exacting demands of incandescent lamp makers. After the Colorado supply of low-grade tungsten was exhausted, some unsalable fines from Dakota were utilized. More recently good ferberite has been purified, but at present this plant is operating at half capacity on Chinese ore, laid down at the plant at a figure less than it can be delivered from mines a few miles away.

CHEMICAL & METALLURGICAL ENGINEERING has already published detailed accounts of the milling practice in Boulder County.* Briefly the process consists of crushing the ore for jigging to about ¼ in. so as to produce the minimum of fines. Jig tails are crushed to about 10 mm., classified, and passed over tables. Table sands are then reground and concentrated as slimes on vanners and canvas tables. Since these articles were published there has been little change in the accepted ideas on gravity concentration—flotation has not been adapted to these ores—but very gratifying results have been obtained by magnetic concentration, especially by the Tungsten Products Co. All its intermediates needing cleaning are dried and then carefully sized in a series of impact screens, and the sized material passed in a thin stream through 3-magnet Wetherell separators adjusted to the product being handled. The first cross belt picks out most of the iron at a low impressed amperage, the second picks up some magnetizable silicates at intermediate amperage, while the last at high density takes out a high grade concentrate, commonly averaging well above 60 per cent, and leaving a tungsten-free residue.

*S. Fisher, "Modern Concentration of Boulder Tungsten Ore," vol. 16, M.S. 15, 1917, p. 959; vol. 17, M.S. 15, 1917, p. 73.

The Tungsten Products Co. also has had success in manufacturing WO_3 by chemical methods and ferrotungsten in electric furnaces, its contracts for the latter having expired only recently. Its plant, in addition to producing tungsten compounds, is busy on experimental work on other electric furnace products. Ferrotungsten is produced by this company in knock-down furnaces of about 100 k.v.a. capacity. A steel shell about 4 ft. in diameter by 4 ft. high, split in halves, is tamped with a refractory lining and placed over a carbon terminal block flush with the floor. A little charge is shoveled in (ore, coke and flux), the single electrode lowered and current turned on. As the charge is reduced more ore is continually added through the open top; the metal accumulates as a button in the bottom of the furnace, while the small amount of slag is tapped periodically through the slot between shell-segments. Metal is left in the furnace, however, and it finally accumulates in the form of a short, thick cylinder, occupying perhaps half the furnace cavity. On cooling, the furnace is torn apart, the slag-free button broken under a skull cracker, further crushed by a steam hammer, and mixed by running through a screening bin and elevator system several times. Ferro is finally shipped to analysis in double canvas bags containing 80 lb. of the alloy.

Government Helium Plants

A recently issued pamphlet on the war work of the Bureau of Mines brings together the personnel and notices the main facts regarding their highly important work on helium. At our entrance into the war there was about 1 cu.ft. of the gas in bottles in possession of Dr. R. B. Moore of the Bureau, probably the available stock on this side. As a starter, however, the British Admiralty requested immediate delivery of 100,000,000 cu.ft., and a weekly supply of 1,000,000 cu.ft.!

Mr. G. A. Burrell, Prof. W. H. Walker and Dr. F. G. Cottrell successively directed the preliminary development of the plans for the so-called "argon" plants, and secured the co-operation of the Linde and the Air Reduction companies. Plants were constructed at Fort Worth, Texas, utilizing the well-known Linde and Claude processes, the former for producing daily 5000 cu.ft. of 90 per cent helium from 0.4 to 1 per cent natural gas, and the latter for producing 3000 cu.ft. per day. Building operations were commenced in November, 1917, and gas was first produced in March, 1918. Both plants were able to make a gas of about 70 per cent purity, which was reprocessed in the Linde plant up to 92 per cent; this stage requiring some two months' experimental operation. Since that time about 200,000 cu.ft. of gas has been made, most of which was in drums at port ready for shipment at the end of the war. Plant 1 (Linde process) has since been dismantled, while the Air Reduction Co. operated a short time working out an improvement in the process, the Navy Department meanwhile taking physical possession of the plant.

Dr. R. B. Moore was given the direction of this work in June, 1918, and was actively in charge for about a year. The Bureau was especially interested in the process devised by F. E. Norton, which had been approved after careful investigation by the National Research Council. In this process triple-expansion engines are used, liquid is throttled and the heat interchanger and fractionating still are of new design. Multiple-expansion engines thus reduce the power for

gas compression to a minimum. However, the development of a new process from laboratory size into the largest refrigerating plant in the world was attended with many difficulties, and the Norton plant (located at Petrolia, Texas) produced helium early in April, 1919. Gas of 21 per cent purity has been made, and it is confidently expected that high-grade gas can soon be produced by this plant on a large scale. A fund of \$100,000 has recently been made available by the Army and Navy for necessary alterations to the plant and its operation as a production unit.

The Navy Department is now engaged in the design of the so-called "Production Plant No. 1" to be situated at Fort Worth. Its daily output will be 30,000 cu.ft., and a supply of 7,200,000 cu.ft. will be required for dirigible use. A modified Linde process will be used, the plant itself costing \$1,700,000, besides \$1,800,000 for a necessary pipe line. It is estimated that operating charges for the production required will total \$750,000, and that the lease on the Petrolia gas field will cost \$1,500,000.

Labor Troubles in Copper Camps

Rather interesting and unusual labor troubles are being endured in Nevada and Montana, but have been treated in radically different ways and with different results in the two instances.

During the last week in July, the shopmen and affiliated crafts of the Nevada Northern Railway, 125 in number, declared an unexpected strike for largely increased wages and certain unimportant changes in the conditions of employment. This railroad, as is perhaps well known, is owned by the Nevada Consolidated, and transports ore from its shovel pit to the mill at McGill, some 50 miles distant, as well as connecting the copper camps with Coburn or Shafter, stations in northwestern Nevada on the Southern Pacific and Western Pacific, respectively, 120 miles north. Although the trainmen were not striking, there was no one to keep the engines in repair or to coal the tenders, so that ore trains ceased to run almost immediately, and a shutdown of mill and smelter was in close prospect.

However, before the stock of ore was exhausted, other unionized employees, from steam shovel operators to converter punchers, united in an ultimatum demanding that a list of concessions and an increase of \$1.25 per 8-hr. day be granted by a specific hour on July 20. The threat was carried out, but the management had anticipated the action, so that the simultaneous stoppage of work of 3000 men in every craft without exception caused no large property damage through frozen furnaces. The company offered an increase of 75c. per day, claiming that this brings the wages to within 25c. of pre-armistice levels, that it is all the present shaky copper market will warrant, and that it re-establishes a scale equal to or greater than the scale paid at any other camp. The men soon receded to a demand of about \$1 per day increase, thus leaving but a margin of 3c. per hr. between work and idleness. Attempted mediation by Gov. Boyle of Nevada and Federal Mediator Davies failed to budge either party to the dispute.

General strike conditions did not become particularly oppressive until the inhabitants began to miss the train service connecting them to the outside world. By permission of the strike committee, trainmen were authorized to take out the passenger trains, but the master mechanic of the railway—the only one doing any engine hosting—was unable to get more than three

trains ready per week. Such conditions were admittedly temporary, however, and complete stoppage of service was in prospect.

A real idea of the gravity of the apparition confronting the citizens of Ely and McGill—300 miles by highway to the nearest considerable city—may be had from merchants' statements before the Railway Commissioners on Aug. 13, that they had supplies of staples for about a week, while dairy products and fresh meats were practically exhausted. One has but to pass through the region to realize that no supplies can be derived from the surrounding country. This condition at Ely but miniatures the state of the whole country in the event of a strike by the railway brotherhoods!

Settlement of the strike on the company's proposals was overwhelmingly voted by the employees after about a month's idleness, however, mining being resumed Aug. 29, and the smelter blowing in on Sept. 8.

A strike of metal workers and stationary engineers against the Anaconda Company on the other hand has not caused material curtailment of production—rather otherwise, strangely enough. Fortunately, the hoisting engineers in Butte are not involved, while mill and smelter men are continuing at work by virtue of signed contracts and tacit disapproval of the walkout by the metal trades. This difference came about over the negotiation of new contracts between company and the disaffected unions, the men feeling that they should receive \$7 per day, while the company offers but \$6.50. Minor questions are also at issue, but the wage rate seems to be the principal bone of contention.

The management has again employed tactics similar to those used in an electricians' strike three years ago; that is, they have called for volunteers among their technical staffs—draftsmen, engineers, chemists and research men—temporarily to take places of the missing mechanics. Of course it is impossible to man the shops completely, and no attempt is made to do any work except that connected with "trouble shooting" and the operation of power houses and substations. From the first, however, all the departments operated with accustomed smoothness, and in fact have readily absorbed the increased volume of ore delivered recently.

Some rather curious things have been demonstrated by this experiment. One is that one electrical engineer can satisfactorily replace about three electricians. Another is that the mysterious comings and goings of the regulation smelter mechanic are more camouflage than the performance of any necessary duties incomprehensible to the ordinary man of ingenuity.

Meeting of Electric Furnace Association

An important reorganization meeting of the Electric Furnace Association will be held at the Congress Hotel, Chicago, at 11 a.m., Monday, Sept. 22. Officers will be elected, and an open session held for discussion of papers on the commercial future of the electric furnace.

Eighth Annual Safety Congress

The National Safety Council will hold its Eighth Annual Safety Congress at the Hotel Statler, Cleveland, Oct. 1 to 4, 1919. A time-table of meetings and programs of the Chemical and Metals Sections will be published in the next issue. During the week of the Congress, the people of Cleveland will endeavor to excel the record established by St. Louis in its "Safety Week" last year. The goal is *no accident* in the week.

Talc and Soapstone Producers' Association

A meeting of all the talc producers of the United States, called by W. C. Boswell, president of the Harford Talc Co., Baltimore, Maryland, was held at the offices of the American Protective Tariff League, 339 Broadway, New York City, on Aug. 12, 1919, when the advisability of forming an association of the talc producers of the United States was decided upon. The protective tariff situation was also discussed.

The following representatives of the leading companies were present:

W. C. Boswell, Baltimore, Md., president Harford Talc Co.
H. B. Barling, Talc Products Co., 11 Pine St., New York, N. Y.

Dr. S. Westray Battle, Asheville, N. C., president Biltmore Talc Co.

Thomas P. Dean, Springfield, Mass., manager Vermont Talc Co.

Michael Doyle, 44 Park Row, New York, president International Pulp Co.

R. W. Glendinning, Los Angeles, Cal., general manager Pacific Coast Talc Co.

Raymond Bardcen Ladoo, U. S. Bureau of Mines, Washington, D. C.

John S. Moore, Johnson, Vt., treasurer American Mineral Co.

R. L. Rutzler, Charlotte, N. C., Oliver Quartz Co., industrial minerals.

W. Edward Seybel, 280 Madison Ave., New York, N. Y., Uniform Fibrous Talc Co.

Frederick Green, Easton, Pa., John O. Wagener & Co., mineral pulp, talc and silicate.

C. J. Zimmermann, New York City, president St. Lawrence Talc Co., Inc.

T. S. S. Predmore, Kinsey, N. C., general manager Alba Mineral Co.

Anglo-American Talc Co., 82 Beaver St., New York City
J. T. Smith, Waterbury, Vt., manager Magnesia Talc Co.

Seven other companies reported by telegram, letter or by proxy, so that probably 90 per cent of the talc production of the country was represented. After discussing the tariff question, the motion to form an association was carried, a committee on organization appointed to draw up a constitution, and the following permanent officers were elected: President, Freeland Jewett (president Eastern Talc); vice-president, W. E. Seybel, and secretary-treasurer, R. B. Ladoo.

The Association of Talc and Soapstone Producers agreed upon at this meeting is the first and only one of its kind in this country. The objects of the association will be the betterment of processes and methods used in the mining or quarrying, and treatment for market of talc and soapstone; technical research into their physical and chemical properties looking toward the discovery of new uses and expansion of markets, and mutual exchange of technical, statistical and market information, expansion of markets through educational advertising, stabilization of markets and prices toward standardization of grades and tests, and the adoption of an efficient cost-keeping method. These objects have not been officially adopted by the producers, but probably many or most of them will eventually form a part of the constitution.

Metallography of Aluminum Ingot—Errata

In the article on the above subject in our issue for Sept. 1, pages 229-234, two unfortunate typographical errors were made which require correction. On page 229, paragraph 2, line 8, the text should read "relatively thick amorphous surface layer is highly undesirable." On page 232, the illustrations of Figs. 23, 24 and 25 should be inverted in order to conform to the description.

Philadelphia Meeting, American Chemical Society

**Report of Council Meeting, General Addresses, Dye Section and Division of Industrial Chemists and Chemical Engineers—Society Protests Against Subordination of Chemical Warfare Service—
Record Attendance—Over 250 Papers Read at Divisions**

THE 58th meeting of the American Chemical Society during the first week in September at Philadelphia was introduced, as usual, by a meeting of the council of the Society. This took place at the Hotel Bellevue-Stratford on Tuesday afternoon, Sept. 2, with President W. H. NICHOLS in the chair. Ninety-seven councillors were present. The editors of the Society's various periodicals were all re-elected, as was also Secretary PARSONS. The name of the Division of Industrial Chemists and Chemical Engineers was changed to the Division of Industrial and Engineering Chemistry. It was determined to hold the next Spring meeting at St. Louis and the annual meeting at Chicago.

Dr. B. C. HESSE was chosen to succeed himself as councillor at large. There are two such councillors at large who, with the president, the two last presidents and the secretary, constitute the advisory committee; a committee that has been in existence only two or three years, but which has been found of great help and convenience in the administration of the Society's affairs.

It was provided that sections of the Society may have associate members who shall have no voting privileges but shall pay not less than \$2 annually. The main purpose of this is to provide for the organization of bodies of men interested in some special field of chemistry which may be more or less localized.

Professor WASHBURN reported on the interallied Chemical Conference, in Paris and London. It is planned to provide for a continuation of International Congresses of Applied Chemistry under the auspices of the interallied body, but no date has been fixed upon as yet. The next meeting is to be held in Italy in 1920.

In regard to the committee on spelling, nomenclature and pronunciation it was resolved to ask the British chemical societies to co-operate. Both Englishmen and Americans will probably follow their national fancies in regard to old words, but there's no reason why they should not unite on new ones, more particularly in scientific nomenclature. It is very important that all English-speaking peoples should understand one another in this respect.

The leading feature discussed was in relation to the proposed bill (S. No. 2715) for the reorganization of the Army. A recommendation has been made by the Chief of Staff, General Peyton C. March, and the Secretary of War whereby it is provided that what is left of the Chemical Warfare Service shall be turned over to the Corps of Engineers. In effect it legislates chemically trained men out of control of the chemical work of the Army and it was held that the matter is too important even to respect West Point traditions. The following telegram was sent to Senator Wadsworth, chairman of the Senate Committee on Military Affairs:

The American Chemical Society, of a membership of over 13,500 American chemists, today by its authorized representatives unanimously adopted the following:

Whereas the recent war has clearly demonstrated that the advancement of science, through competently directed research in military problems, is indispensable to the security of the nation, and

Whereas the bill recently introduced into Congress, Senate 2715, 66th Congress, by the General Staff of the Army, providing for universal military service and the reorganization of the Army, is of such scope and effect as to impede inevitably the development of all technical and scientific work of the Army by placing

it under the absolute control and direction of purely military officers who do not have the requisite scientific knowledge, and

Whereas an organization so constituted could not function efficiently, and in time of stress would prove to be an element of fatal weakness and could never hope to attract to itself other scientific and technical experts without whose aid modern warfare cannot be successfully conducted; now, therefore, be it

Resolved, That the American Chemical Society emphatically protests against this or any other bill which does not provide for commissioning staff officers in the corps and departments in which they are to serve, and which does not accord to the technical men the same recognition and opportunity throughout every grade and department of the Army as are accorded to the men trained for a military career only.

We have written so much in favor of this very attitude that we take pleasure in confirming it. It has nothing to do with urging gas warfare upon military authorities, but it does urge upon the Government the necessity of being prepared against it, and the only way to do this in regard to chemical problems is to have it done by chemists in a chemical division and under the supervision of chemists rather than of engineers.

The Council was entertained at dinner by the Philadelphia and Delaware Sections.

THE GENERAL MEETING

The general meeting of the Society was called to order Wednesday, Sept. 3, at 10 o'clock by Chairman MINER, who after a few words of welcome introduced the Hon. JOSEPH S. MCLOUGHLIN, Director of Supplies of the City of Philadelphia, who spoke on behalf of the city. To this President NICHOLS responded in appreciation and introduced the Hon. NEWTON D. BAKER, Secretary of War.

Secretary BAKER said that of the 17,000 chemists of the United States one-third had been in uniform in the Government service and one-third had been engaged in war industries. He doubted if any profession had contributed more to military service or to our national success in the war than the chemists. He outlined the plans for the future of the Army. As an instance of the requirements of war he related the fact that to support a 3-in. gun with ten men at the front there

is needed a factory with 300 operatives. The proposed law was not dealt with in detail, in fact the question of disposal of the Chemical Corps was hardly touched upon except for the fact that it is evident in the mind of Secretary Baker that ample provision is to be made to maintain scientific standards. We understand, however, that the Chief of the Engineers does not want the Chemical Division and the former heads of the Chemical Divisions have expressed themselves against the proposed law in its original shape. It may be that the Honorable Secretary in time will see over the heads of his staff officers and realize that a West Point man with all the responsibilities for canal and river and harbor improvements is no more peculiarly equipped to direct chemical research than he is to direct medical research. The new plan for the Army provides that there shall be a great educational institution, taking young men on to serve for a few years and sending them back to civil life well equipped with a craft. They plan to build a vast engineering school to include chemical as well as other branches of engineering and they expect to maintain a great research establishment to which the leading men of the country are to be invited to work and to exchange views with military men. The address was very appealing and masterful and contained many interesting facts. For instance, there are from 9 to 10 million men, young men, dead from the war, and its cost is 2 million million dollars, whereas all the property of the U. S. is valued at 186 thousand million dollars. There was a lower percentage of suicide, insanity or crime in the U. S. Army than in any other army or any known similar number of civilians.

The Secretary of War received the sincere applause and appreciation of all present, except in regard to that feature of his Army bill that seems defective in its provision for chemical research.

Admiral RALPH EARLE, Chief of Ordnance, U. S. N., followed the Secretary of War and gave a full account of the use of explosives by the Navy. What is now needed is a smokeless powder that is not accompanied by a blinding flash when heavy charges are delivered.

Dr. H. J. WHEELER spoke on "Some Problems and

Methods in Agricultural Research." The address was in part historical in regard to agricultural chemistry in this country, but a number of present problems were outlined. He called, for instance, for research in regard to waste plants and waste plant products. There is promise in the utilization of milkweed, and, again, it is possible that values may be found for the Southern water hyacinth, which grows with extraordinary vigor. There is need for further research in regard to the chemical effect upon soils of lime, for instance, and in regard to the causes of acid conditions. Leadings are already provided for in these respects. Thus liming has been found to be detrimental under certain conditions and occasionally to incite plant diseases. In Hawaii the presence of an excess of manganese prevented the absorption of iron and the consequent production of chlorophyll, which was overcome by treating the leaves with a solution of iron. Only this year it was discovered that potash from Searles Lake frequently had a toxic effect which was found to be due to the presence of borax. More research is needed as to the effect of boron and borax upon vegetable life. Occasionally it appears that well-drained upland soils become acid, and Hartwell and Temper of Rhode Island have shown that often the toxic effect is not due to acidity but rather to the formation of aluminum sulphate. Sometimes, too, aluminum nitrate is formed, and that also acts as a poison. Study is needed as to the effects upon all kinds of plants of aluminum compounds and the lower oxides of iron.

The Department of Agriculture has found a large number of organic compounds in the soil which are deleterious in their nature. For instance, leachings of soil in which grass grows have been found injurious to many kinds of trees. One of the difficulties in regard to agricultural research is that the salaries paid to men of wide learning and experience are less than those paid for common labor.

Professor EARLE B. PHELPS spoke of "Stream Pollution and Its Relation to Chemical Industries." He believed that the drafting of legislation in regard to stream pollution should be in the hands of an intelligent board such as the River Board of Great Britain, and recommended that the subject be placed under Federal control.

BUILDING OF ATOMS AND THE PERIODIC SYSTEM

Professor W. D. HARKINS of the University of Chicago delivered a very interesting address to a capacity audience on "The Building of Atoms and the Periodic System." His theory in regard to the constitution of atoms has been published from time to time chiefly in the *Journal of the American Chemical Society*, but a number of new and very interesting points were brought out. Professor Harkins postulates that the helium atom is the product of combination of hydrogen atoms and that other elements are either combinations of helium atoms—which are the even numbers—while those having odd numbers are combinations or rather amalgamations of helium atoms with those of hydrogen. Elements of even number are much more prevalent than those which are odd. Differences of the atomic weights of elements of even number of approximate multiples of 4 are offered in confirmation. Still another confirmation is the successful experiment of Sir Ernest Rutherford, lately achieved, whereby he shot alpha particles at great speed into a glass tube containing nitrogen. The walls of the tube were sufficient to bring the particles to a

standstill. Nitrogen being an odd element (number 7) is held to be made up of three helium atoms and two of hydrogen. The impact of the alpha particles which, being positively charged, may serve as nuclei of atoms, disintegrated the nitrogen so that a quantity of hydrogen was found in the tube.

Mr. ROBERT R. FISHCELIS followed with a short paper on "The Chemical Laboratory as a Publicity Factor."

Social Features

The smoker was one of the best ever held by the Society and the entertainment provided was at once instructive and amusing. The singing was led by a song leader of the War Camp Community Service, and the songs, both originals and parodies, were unusually good. The reader can imagine, for instance, what an excellent parody on "Smiles" can be made by a chemist who is familiar with "smells."

One of the features of the smoker was a one-act play portraying an early chemists' meeting in the cellar laboratory of Robert Hare, Jr. at the time when Dr. Joseph Priestly came to Philadelphia. Not the least instructive feature of the smoker was a series of animated mechanical films by the Bray Studios.

The banquet on Friday night was a brilliant affair. Dr. Harry F. Keller acted as toast-master and introduced Dr. Edgar F. Smith, Provost of the University of Pennsylvania, who responded with a few brief references to the life and work of Robert Hare, an early

ROBERT HARE (1781-1858)

Philadelphia chemist. Following Dr. Smith's remarks each one present was given a steel engraving of Robert Hare, a copy of which is reproduced with this report.

Mr. Ellwood Hendrick, consulting editor of *CHEMICAL & METALLURGICAL ENGINEERING*, responded to the toast "The Chemist of the Future" and emphasized the need which the chemist has of someone in his profession to speak with the voice of authority. Following him the Hon. Edward E. Beidleman, Lieutenant-Governor of Pennsylvania, spoke on some phases of the present industrial conditions, saying that we must quit playing to the galleries on political issues, study civic problems

and increase production. Dr. Harlan S. Miner, presiding officer of the Philadelphia Section, responded for the Section and told something of its work. Mr. Edward James Cattell, Philadelphia Statistician, made one of his characteristic humorous speeches. He was followed by Dr. Charles L. Reese, the presiding officer of the Delaware Section, who told of this infant organization which has over 400 members.

The program of the evening was closed by speeches from the only surviving charter members of the American Chemical Society, Dr. Charles F. Chandler and Dr. William H. Nichols. The latter suggested that one of our industrial troubles is due to the high cost of loafing and that a suitable remedy would be to stop loafing and substitute efficiency in our industrial life.

The all-day boat ride on the Delaware River, tendered by the Delaware Section, afforded an excellent opportunity for making acquaintances and talking over technical problems. The boat left Philadelphia at 9:45 A.M. and made a round trip to Deep Water Point. This afforded an opportunity to gain an idea of the extent of the chemical industries along the waterfront.

Presidential Address—Research and Application*

BY DR. WILLIAM H. NICHOLS

For nearly half a century, it has been the custom in this Society to give its president every year "his day in court," and in conformity therewith many brilliant addresses have been delivered, and almost every conceivable subject has been discussed. It is therefore becoming more and more difficult for the incumbent to select a theme which shall have the merit of novelty, unless, perchance, he is himself working in the laboratory, and can bring forth some new and shining example of the progress of his science. I have not the good fortune to be so situated, and I must perforce satisfy myself with some other line of procedure in the hope that even in a discussion of old and well-known facts, some new light may be thrown, which will not be altogether without value. I have therefore selected for my subject, "Research and Application."

Research in the distant past was the privilege of the few. In chemistry, during the Middle Ages, the alchemists were practically the only ones pursuing it,

ANNUAL BANQUET, AMERICAN CHEMICAL SOCIETY, SEPT. 5, 1919, AT BELLEVUE-STRATFORD, PHILADELPHIA

A stop was made at Hog Island, where the *Sinsinawa* was launched. A complimentary box lunch was served on the boat.

Entertainment for the visiting ladies comprised several luncheons, automobile rides, a theater party, and an organ recital. The ladies also attended the banquet and river excursion.

The local Section is to be commended for its support of a daily issue of the *Catalyst*, which is the official bulletin of the Philadelphia and Delaware Sections. This contained registration lists, reports of meetings, announcements of programs, and last-minute information on convention details. This excellent feature of the meeting was in charge of the editors, Sydney Davis, Robert P. Fischelis and F. C. Zeisberg.

and they in secret, and not always from the highest of motives. Working by themselves, as they did, they had not the great advantage of meeting and discussing with others similarly engaged, and using their progress and mistakes to intensify their own increase in knowledge. Thus it has come about that the science of chemistry is little more than a century old, and its tremendous advances only a few decades. The first chemical society in the world was born in Philadelphia in 1793, and yet the real advances have been made since the formation of this Society in 1876. Since that time, however, the advance in knowledge has been startling, not alone in this country, of course, but in all civilized countries.

*Abstract from the paper read before the American Chemical Society, Sept. 4, 1919.

It is not boasting to say, however, that during all that time, the progress in this country has been in nowise behind that of the best anywhere, which our public is at last beginning to recognize. Particularly during the trying period of the war, when vast and new problems were suddenly thrust upon them, the work of our chemists has been beyond praise.

At the foundation of all this advance, research is firmly imbedded.

No one can deny that there have been accidental discoveries, some of great moment; but this has not been and will not be a safe dependence. Accidental discoveries are not to be relied on, of course, although they are not to be scorned. In chemistry the accidental good fortunes have usually come to those who were really seeking, although possibly for something far different, but, note this, they were usually made by men qualified to recognize an important discovery when it flashed across their vision.

Research, of course, is not of necessity to result in

education which produces real practical knowledge is absolutely essential. All agree, also, that the person to be prepared must be a likely subject; and that energy and time should not be wasted on those who do not show that they possess certain necessary qualifications. I think that it will also be generally admitted that the teacher himself should not only have great attainments, but must also possess the rare quality of being able to transmit knowledge in such a way that it will be truly absorbed by the pupil and form part of him. One of the greatest mathematicians I have ever known was about the poorest teacher. He knew but could not impart. The future of the world, therefore, depends in a very large degree, on the teacher in the school and on the professor in the college. They have an opportunity to mold the world, which many of them thoroughly appreciate. Alas, in most instances, the consciousness of work well done is about their only reward. Some day, and I hope not a very distant one, it will be generally recognized that, like other

invention. It may in that respect terminate in a cul-de-sac, from which, with present knowledge, there is no egress, or what more frequently happens, it may lead to a line of reasoning, which in time leads to another, and so on, until suddenly a bright light illumines the way, and a goal of the greatest possible importance is attained. Many instances illustrative of this will occur to you.

True research must be intentional and intensive. We must have imagination, it is true, but we must have more than that. There must be the foundation of sound education, and the ability to extend it to embrace new and unexpected knowledge, and apply this in turn as we progress upward.

To fit a man for research in chemistry or any other science, many things must be accomplished before the candidate is ready to take his first advanced step. Many methods of procedure have been suggested, and some heat of argument generated; but all agree that

laborers, they are worthy of their hire, and their compensation will more nearly approximate the value of the work done. When that happy day arrives, they may experience a little less of the satisfaction of sacrifice, but they will have other comforts and hopes which will more than make this up to them and to their families. Like others before me, I advise the people of this country that they can make no better investment than one liberal enough to cause the teaching profession to attract not only those whose high sense of duty leads them to embrace it at a sacrifice, but also those who cannot afford to make the sacrifice, however anxious they may be to do so. Men preparing for research must have the best men in the country to guide them, and it is not fair to expect these men, as so many have done in the past, to live the narrowing life of poverty. Neither is it wise.

There are a few foundations specifically provided for chemical research, such as the Warren Fund of the

American Academy of Arts and Sciences, the C. M. Warren Fund of Harvard University, and the Wolcott-Gibbs Fund of the National Academy of Sciences. There are a number of foundations for promoting research generally which have included chemical research within their fields, such as the Bache Fund of the National Academy of Sciences and the Elizabeth Thompson Science Fund. The Rockefeller Institute for Medical Research fosters chemical research contributory to its main object, the Carnegie Institution of Washington supports chemical research in its general policy of advancing knowledge through research. The newest of all is the fund recently placed at the disposal of the National Research Council for stimulating chemical research. There is need for many more foundations if we are to keep pace with the rapid strides of civilization, or better still, to determine the direction they will take.

The importance of research is being more and more recognized and understood by the public. One of the

the welfare of the nation is many times greater than the cost of the necessary research; and

Whereas the increased productivity of industry resulting from scientific research is a most potent factor in the ever-increasing struggle of the workers to raise their standards of living, and the importance of this factor must steadily increase, since there is a limit beyond which the average standard of living of the whole population cannot progress by the usual methods of re-adjustment, which limit can only be raised by research and the utilization of the results of research in industry; and

Whereas there are numerous important and pressing problems of administration and regulation now faced by Federal, State and local governments, the wise solution of which depends upon scientific and technical research; and

Whereas the war has brought home to all the nations engaged in it the overwhelming importance of science and technology to national welfare, whether in war or in peace, and not only is private initiative attempting to organize far-reaching research in these fields on a national scale, but in several countries governmental participation and support of such undertaking are already active; therefore be it

most encouraging evidences of this is shown in the preamble and resolution adopted recently by the American Federation of Labor at Atlantic City, indicating, as these do, a clear appreciation by that great association of how much we all depend on what science will disclose to ameliorate the conditions of the future. It is well worth while to read these in full here. They are as follows:

Whereas scientific research and the technical application of results of research form a fundamental basis upon which the development of our industries, manufacturing, agriculture, mining, and others must rest; and

Whereas the productivity of industry is greatly increased by the technical application of the results of scientific research in physics, chemistry, biology and geology, in engineering and agriculture, and in the related sciences; and the health and well-being not only of the workers but of the whole population as well, are dependent upon advances in medicine and sanitation; so that the value of scientific advancement to

Resolved, By the American Federation of Labor in convention assembled, that a broad program of scientific and technical research is of major importance to the national welfare and should be fostered in every way by the Federal Government, and that the activities of the Government itself in such research should be adequately and generously supported in order that the work may be greatly strengthened and extended; and the secretary of the Federation is instructed to transmit copies of this resolution to the President of the United States, to the President pro tempore of the Senate, and to the Speaker of the House of Representatives.

I hope and believe that this matter, coming as it does from a new direction, will be most seriously considered by the proper authorities—not that it has not already been well understood in Washington, but that renewed interest may be taken and even more liberal appropriations granted. The Federation resolution urges that "a broad program of scientific and technical research is of major importance to the national welfare." Good! Now that everybody is agreed, how was it possible

that for so long a time this belief was held by so few, and these composed almost entirely of men of science? The question, therefore, is squarely before the country, and the urgency of it thoroughly appreciated by those who have the most to gain by it; namely, the workers on whose efficiency so much depends. Now this opens the way to a scientific solution of vital questions about which there has been such fundamental differences of opinion, based largely on what may be called the point of view.

CAPITAL AND LABOR

People have divided themselves into classes—a very dangerous course—and many, a very great many, have actually believed that there must of necessity be a deeply rooted difference between capital and labor, and that the true interests of either were entirely apart from those of the other. Many have held that labor is a commodity which it was to their best interest to get the most of for the least money, while many others believed that labor was the sole source of all wealth, and that the fewer hours worked, and the smaller the output of those hours, the better it would be, somehow or another, for the laboring classes. I have cited the extreme views for purpose of illustration, realizing that somewhere between the two would be found the great body of all reasonable and thoughtful men. We may leave out of consideration here that ultra-extreme class who teach, whether they believe it or not, that the true interests of labor would be best served by sabotage and syndicalism, and all the other fantastic notions which have of late years been more or less in evidence, and liable to catch the unwary. To these, research presents no attractions.

CO-ORDINATION OF STUDY AND PRACTICE

Now I am going to venture to suggest to the workman who is earnestly desirous of bettering his own and his family's condition that there are a good many sciences besides chemistry and the engineering and abstract sciences in general. Some of these he is better able to study and practice than any one else. Many of the fundamental truths concerning labor and its conditions would never be discovered by the scientist *per se*, because he has not had the benefit of practical preparation. Let our friends of the American Federation of Labor not be content with what the Government can do in the line of their resolution, good as it has been and will be, but let them start a carefully planned series of researches themselves, and follow them up until the truth stands revealed. They can depend upon the assistance of this great Society. The employers of labor have been doing this for years, singly and in groups, seeking the same end. The shining goal of all research is the truth, the whole truth, and nothing but the truth. Thus, starting from different angles, with fairness and thoroughness, the various so-called interests will arrive at the same truth, for there can be only one truth concerning any question. Thus will it come to pass that capital and labor will discover that the true interest of one is the true interest of all, and instead of bickerings and suspicions we will have that cordial co-operation which is absolutely essential if we would get the best out of this good old world.

Research leads to discovery. Discovery to invention. Invention—no one knows where. Applied and supervised by those prepared for the task, the strides of progress will be long, and the benefit to the human race in proportion.

Papers Read Before the Divisions

About 250 papers were given before the ten divisions, so that the best those who attended the meeting could hope to do was to hear about one-tenth of them.

A report on the Division of Industrial Chemists and Chemical Engineers and the Dye Section is given below. The Rubber Division will be reported in a following issue. A few notes taken from papers of other divisions are given, but these were not made complete, as many of them will be published in full in the near future.

USES FOR SHARKS

ALLEN ROGERS of Pratt Institute in an interesting paper before the Agricultural and Food Division on the utilization of sharks drew attention to the importance of overcoming modern prejudices against the shark and stated that from time immemorial the shark has been considered as an enemy to man and as a scavenger of the sea. It has been pictured as the cannibal of the deep, and in fiction has been painted as the vulture which lurks about the ill-fated ship in order to devour the unfortunate who may have met their death in the gale or on the reef. We, therefore, for generations have cherished an antipathy for this animal of the sea and have been very willing to accept as fact all of these stories, never stopping to consider that perhaps after all the shark might have a few good points in his favor.

The Bureau of Fisheries for several years has endeavored to interest the people of this country in the use of shark meat as an edible product, with a certain amount of success. In fact, that species of shark known as dogfish is being canned in large quantities and sold under the name of grayfish. Certain fisheries on the New England coast are removing the head, tail and fins and selling the product in Boston and New York as deep sea swordfish. In Boston also shark meat is being sold as such to the Italian trade, who appreciate its food value and enjoy its delicate flavor. Why then should we not take a lesson from the Italians and acquire the shark-eating habit?

For the past five or six years Dr. Rogers has been interested in developing a method for converting shark skins into a merchantable leather. As a result of this work several processes have been devised which have been assigned to the Ocean Leather Co., operating fisheries at Morehead City, N. C., and Fort Myers, Fla. This concern alone expects to get up to a catch of 1000 fish daily, although at present it is not taking this number. The skins are now being manufactured into leather, the livers rendered for their oil and the flesh converted into fertilizer stock. It is estimated also that at least 1000 sharks can be secured daily from the fishermen handling food fish, who at present simply kill the sharks getting into their nets and throw them back into the water. By this wasteful procedure on the part of the fishermen at least 1000 sharks daily are destroyed along the Atlantic coast. Thus not only is the skin lost to the leather trade, not only is the liver oil discarded, not only is a large amount of fertilizer material made unavailable; but at least 50 per cent of the weight of shark which would be fit for human consumption goes to waste.

A conservative estimate based on the above figures indicates that for a catch of 2000 sharks daily, at an average weight of 200 lb., there would be 400,000 lb.

of fish. As at least 50 per cent could be used for human consumption, we would have 200,000 lb. daily, or 73,000,000 lb. annually. Assuming that the market price could be set at 10c. we have a saving of \$7,-300,000.

The question of supply is one that is constantly being asked. From personal observations and from those who are most familiar with the subject, it seems evident that the supply is inexhaustible. Another question is often raised as to the best method to prepare the flesh for market. The answer is cold storage. This method, however, may not always be practical in isolated fishing stations. Recourse must then be made to salting, smoking or drying. The fresh meat, however, is the most delicious, and when boiled, broiled or baked furnishes a white flaky food closely resembling halibut or swordfish.

A source of food supply so extensive warrants our most careful consideration, and it is hoped that the time is not far off when we may overcome our prejudice and take advantage of nature's abundant supply.

GREATER EFFICIENCY NEEDED IN THE CHAMBER PROCESS

ANDREW M. FAIRLIE of Atlanta in his paper before the Fertilizer Division on the conservation of salt-peter in the chamber process stated that 14 per cent of the nitric acid in the Gay-Lussac towers was lost per cycle, and in connection with the prevalent protest against the high cost of food, means for conserving nitrate of soda in the manufacture of sulphuric acid has twofold interest.

The lowest possible consumption of nitrate of soda in the manufacture of sulphuric acid means low cost for producing the acid, and, as sulphuric acid is the principal item in the cost of making acid phosphate, cheaper sulphuric acid should result in cheaper phosphate, and cheaper phosphate should result in cheaper food.

Nitrate of soda is itself an important ingredient of fertilizer, and any decrease in the consumption of nitrate for making acid should react in favor of a decreased demand, and so of a lower price, for nitrate of soda.

The various methods of introducing nitrogen compounds into the acid-making process were reviewed, and the methods in common use for controlling the chamber process briefly described. Attention is directed to the gradual extension of the analytical method for chamber-process control, and to the improved results attained where this result has been adopted. The Gay-Lussac tower, as a means of recovering the nitrogen compounds, is not an ideal or yet an efficient piece of apparatus, and the need exists for either an improved type of Gay-Lussac tower, an auxiliary to the Gay-Lussac tower, or a substitute for that tower, capable of effecting a higher percentage of nitrogen recovery.

SLIDE RULE FOR CALCULATING SO CONVERSION

F. C. BLAKE of Wilmington in his paper before the Physical and Inorganic Division on the construction of special slide rules for chemical calculations gave a description of two rules. The one on SO_2 conversion to SO_3 should be in general use in sulphuric acid works.

In general, if an equation can be written in the form

$$f(x) = f(y), f(z)$$

a slide rule may be constructed so that the value of

any variable may be found if the others are known. As a simple illustration, consider the computation of conversion in the contact process for the manufacture of sulphuric acid. Let

a = per cent by volume of SO_2 in entrance gas

b = per cent by volume of SO_2 in exit gas

c = per cent conversion = per cent of SO_2 converted to SO_3 .

These quantities are related by the equation

$$c = \frac{10000(a-b)}{100a - \frac{3ab}{2}}$$

This form of equation is not suitable for the construction of a slide rule, but it may be rewritten as

$$1 - \frac{c}{100} = \left(\frac{100}{a} - 3 \right) \div \left(\frac{100}{b} - 3 \right)$$

SO_2 - SO_3 RULE SET, 10 PER CENT ENTRANCE, 0.7 PER CENT EXIT EQUALS 94 PER CENT CONVERSION

The slide rule scales for the solution of this equation are in the accompanying figure. The upper scale

is laid off proportionally to $\log \left(\frac{100}{a} - 3 \right)$ the slider to $\log \left(\frac{100}{b} - 3 \right)$ and the lower scale to $\log \left(1 - \frac{c}{100} \right)$.

These scales are laid off from right to left so that the marked values a , b and c will increase from left to right, as this is the most natural method of reading scales. The proper values of SO_2 in burner gas and exit gas are set together and the conversion read opposite the arrow. The zero point (i.e., $\log 1$) of the lower scale is moved to the left relative to the upper one to make the rule more compact and the arrow displaced the same distance to give the correct reading.

The Dye Section

The meeting of the Dye Section was so well attended that it was necessary to move from the little "Green Room" set apart for it to one of the large restaurant rooms on the main floor. Dr. CHARLES L. REESE, the chairman of the Section, presided. In his introductory remarks he said that some two or more years ago he told the American Cotton Manufacturers Association what American chemists could do for them, and he was now ready and willing to review what they had done for them in the meantime. There is some \$100,000,000 invested in the American dye industry, and it has taken the courage of conviction to make these ventures. Every new industry has high production costs in the beginning and manufacturing units have to be made small to avoid extraordinary losses. Manufacturing costs, however, are improving. He explained the origin and workings of the Chemical Foundation, discussed the licensing system as developed in England and predicted that within another year's time the dye industry would be much further advanced. Indanthrene dyes (a type of the much needed fast cotton vat dyes) are

being produced today and he believes that in six months the consumer will have all of these that he desires. This belief was later confirmed by Dr. GRINNELL JONES, who said he had seen factories at work producing vat dyes and large works already built and ready to begin. There is more indigo made in this country today than was imported before the war.

Major T. H. SILL followed with an address on "The Present Condition of the German Dye Plants." In February and March of this year Major Sill inspected the leading German dye plants to observe what they had done in war. He was under the impression that they were in pretty bad shape, but soon found them to be in perfect operating condition, except in a few minor details. They retain their complete forces, and owing to the stress of war, the plants have been enlarged. They are operating on only about 10 per cent of a peace basis, but they keep their labor occupied in cleaning and polishing and away from bolshevist agitation. Result is everything is remarkably cleaned up. At the time their only shortage was zinc dust, pyrites and chrome ore, which they can probably get now. They were also short of lubricating oils.

The best and most modern of the German works is the Bayer establishment at Leverkusen, opposite Cologne. Their offices and clubs for workmen are almost palaces and the place is nearly a city by itself. One of the first persons he met was Prof. Duisberg, their managing director, who will be remembered by those who attended the Eighth International Congress of Applied Chemistry in New York in 1912 as providing a perfect specimen of German competence and boastfulness. The genial Dr. Duisberg assured Major Sill that as for the Bayer works, they were really such novices at the art of making poison gases that they could hardly be reckoned as a factor in it. The Major soon learned, however, that this same Bayer Co. had been leading producers of mustard, diphosgene, etc. The Bayer Co. has been making artificial rubber at the rate of 150 tons a month. The price has been high—30 to 40 marks per kilo—but this, it is believed, will soon be greatly reduced and the company expects to compete with natural rubber. Another very interesting development was the manufacture of 1000 tons per month of sulphuric acid from gypsum.

The establishment of Weiler ter Meer at Merdingen he found well kept up and that it had in 1918 erected a palatial clubhouse for its workmen.

Kalle & Co. at Bieberich looked run down and delapidated, but the Hoechst works, formerly Meister Lucius & Brüning, had had a wonderful development, doubling their employees from 8,000 to 16,000 men. They were pioneers in making poison gases and oxidized vast amounts of ammonia to nitric acid. This concern is in excellent condition.

The Badische Aniline & Soda Fabrik at Ludwigs-haven employs about 16,000 men, and it is older and more congested than the Bayer works. It has continued to make dyes during the war and it is said to have not only a large accumulation of dyes but still greater stores in the interior of Germany. A little further up the river is the \$75,000,000 Haber process works of which the research laboratory alone cost over \$1,000,000. Here and elsewhere in Germany there were some 650 tons of ammonia per day produced. The country has been producing more ammonium products than before the war.

Major Sill did not believe that the layout of the German plants was better than those of America, although in addition to the advantage of experience in technique they have certain features that are improvements over American practice. Among these he mentioned the habit of building water towers around chimneys and thus utilizing a good part of the heat; a better distribution of filter presses, a novel nitration system and remarkably high-grade lead fittings. On the other hand, they lack elevator and conveying machinery and there is a great deal of transportation of materials from plant to plant which would never do in this country.

These German plants, he said, owing to their equipment, their competent staffs of chemists and their chemical versatility, constitute the technical reason why there lie 38,000 of the flower of American youth dead in France, with a far greater number maimed. It was one of the directors of the Badische Aniline & Soda Fabrik who lately said: "We [Germans] need be in no terror as to the future of our dye industry. American textile manufacturers will not continue to pay high prices, and when the markets are open, so-called patriotism in that country will vanish like hoar-frost on a sunny Spring morning."

At this point Dr. Reese observed that while prices of American dyes might be higher for some time to come, the German product would have no advantage whatever as to quality.

Dr. J. MERRITT MATTHEWS gave a review of the dye situation.

We have discovered, he said, that the real secret of German success was to be patient in research and to carry research into the factory. A study of the dye census of 1918 shows that the American industry supplies a large proportion of the colors needed. The development has been somewhat one-sided, but this has been for economic reasons. In England they have brought out a good range of vat dyes and of true alizarine colors; on the other hand, the American development has been greater in azo and direct cotton colors, also in fuchsine and color lakes for paints and printing inks. Rating the American industry as 100 per cent, he thought the British coal-tar color industry will represent 50 to 75 per cent in comparison. France was like the rest of us before the war and expanded less for self-evident reasons. Since the armistice she has gone ahead, her chief accomplishment being the production of indigo. Other dyes are less important in quantity. The close relations with Switzerland are already shown in the establishment of a branch in France of the largest Swiss works, the Society of Chemical Industry of Basle. It is likely too that the French oversight of the Badische will provide for some French chemists some important hints as to technique. Japan is a newcomer in the industry and has but one really effective establishment. That country is making less headway than the others.

We must bear in mind that the world market for dyes is not capable of very great expansion. Before the war Germany supplied from 80 to 90 per cent of the world trade. The Germans can soon reach greater production than before, and they are ready to go ahead again. Great Britain has laid out plans to take care of its home and colonial markets. And it will. The capital invested is large and the British government has gone into the partnership. It is a foregone conclusion that

the British and Colonial markets will be withdrawn from the world's trade. And they will have a surplus to offer for the international demands.

In this country, Dr. Matthews figured, \$60,000,000 to \$80,000,000 has been invested in the industry. The capacity is large and it is growing. With proper encouragement from the Government he believes that in all events in a few years if not, as Dr. Reese believes, in a few months time, the gaps will be filled up. It can easily care for the American market and export the surplus.

France is resolved to develop, but it may use Switzerland in part and it may take dyes from Germany in part payment of indemnity. The Swiss have increased their coal-tar color industry threefold since the war and will probably rank next to Germany in efficiency and economy. So we shall have, competing for the world's market, Germany, Switzerland, the United States and England for certain and possibly France and Japan. Roughly, it may be divided as continental Europe 20 per cent, Great Britain 15 per cent, United States 12 per cent, Asiatic countries 45 per cent, South America 5 per cent, Africa 3 per cent. Only half of the world's markets are open, while productive capacity has increased threefold. Now, the salvation of the industry lies in intense research to develop uses for all by-products and raw and useful products from the same materials so that the making of dyes becomes incidental to the making of many other useful things.

Dr. GRINNELL JONES of the Tariff Commission discussed the progress of the dye industry as shown by the Commission's census of 1918. The production of benzene and toluene has far outstripped the needs of the color industry, being 52,000,000 gal. benzene and 14,000,000 gal. toluene in 1918. Five firms produced crude anthracene, but their joint product was less than 250,000 lb., which is not enough. The situation is improved. Carbazol was also first produced in 1918, but we are still short of carbazol products. A decrease is shown in the production of the easiest intermediates to make, but this is compensated for by the increase in more difficult intermediates and dyes made from them. This indicates an improvement in the kinds of dyes made. Another good feature is the decrease in the prices of dyes and intermediates despite increased costs of labor, construction and transportation. This means making steps toward a true competitive basis. Dr. Jones has seen a number of plants designed by German and Swiss chemists which were redesigned by American chemists to their great advantage in the economy of labor.

Mr. R. S. LUNT spoke of "The Quality of American Dyes," and declared that shipments are now running fully as close to standard as before the war.

Mr. H. A. LUBS reported a new series of indicators and Mr. H. D. GIBBS described the work of the color laboratory of the Bureau of Chemistry at Washington, D. C.

On Friday morning the Dye Section crowded the large dining room on the main floor of the Bellevue-Stratford. Dr. W. F. EDWARDS urged standardized tests for dyed goods in order to break down the prejudice against American-made dyes. Retailers, in order to avoid responsibility for the color quality of goods sold, declare that American dyes are not dependable and that their customers must take their chances in this respect. Now it is very easy to determine the color quality of cloth; just as easy as it is to make very simple

steel tests, and the processes are inexpensive. The only thing required is an agreement upon standards, and it is to be hoped that the Dye Section of the Society will take the matter up and provide for this much needed achievement.

Dr. E. W. PIERCE of New York presented a very interesting historical paper on "The Application of Dyes." We shall only note that the reason why the dyeing of Tyrian purple remained a secret and that the dyers of it were social outcasts was because a putrefactive process was employed which rendered it next to impossible for anyone to go near the dye houses or to the men who worked in them.

One of the most interesting papers was presented by Mr. EDGAR T. WHEERRY on "Crystallographic Identification of Five Isocyanines." He found that in the five instances mentioned, the identical substance might show a marked difference in the color of its crystals; that different batches of the same substance would vary from yellow to purple. This phenomenon, he said, was due to reflectional pleochroism, in which the color of reflected light varies according to the plane reflected to the axis of the crystal. Thus the color would range from yellow to purple as the crystalline habit developed one set of planes or another. This rare phenomenon explains the fact that a dye may vary in the color of its crystals while remaining the same in chemical structure and tinctorial effect.

Mr. W. H. WATKINS of the National Aniline & Chemical Co. presented a paper on "Observations on the Estimation of the Strength of Dyes." It was a contribution of great practical value, providing methods for adjusting differences between buyers and sellers.

Mr. E. K. STRACHEN of Buffalo, also connected with the National Aniline & Chemical Co., spoke on "The Application of Physical Chemistry Research on Dyes." This was of the sort to make our old-fashioned color chemists sit up and take notice. A number of very valuable curves were shown.

Division of Industrial Chemists and Chemical Engineers

The earnestness of endeavor of the members of this section and the successful work which they are thereby accomplishing was clearly demonstrated in the number and high character of the papers presented at this meeting. It seems truly marvelous that the wide field embraced should be so thoroughly covered in the short time allowed for the deliberations, and the result can only be attributed to the fact that each individual member, upheld by highly developed imagination, is following the ideal of benefit to the industry without thought of self. The direction of the work was carried on under Dr. H. S. MINER, chairman, with H. E. HOWE secretary. Two symposiums and 27 papers were presented. Abstracts of a few of these are given below.

Gas Masks in the Industries—A. C. FIELDNER. In order to promote the development of safe and suitable designs of gas masks of the Army type for industrial use, the Bureau of Mines has established a gas mask department at the Pittsburgh Experiment Station. The Bureau will co-operate with manufacturers of gas masks in approving them for use in the gases for which they are intended provided they pass the tests prescribed in Schedule 14. A 1000-cu.ft. gas chamber has been installed in which masks can be tested in various concentrations of any gas desired. Other equipments

for making mechanical and chemical tests are also provided.

Division of Industrial Research. National Research Council—H. E. HOWE. The speaker explained that this division is not a Government department but an organization with the purpose of developing research for the common welfare of the country's industries.

The Council will not itself maintain laboratories for conducting research, but will function to encourage research by men of the industry. It will accomplish this in making public the work done by others through the medium of pamphlets and data published in the columns of the American Chemical Society's journals.

The Value of Cost Accounting in Commercial Laboratories—WILLIAM W. CASWELL. Cost accounting systems, long considered an unnecessary frill and a burdensome evil, have come to be recognized as an important requirement in the conduct of general business institutions. Statistics show that of the 250,000 corporations doing business in the United States only 125,000 are making money, and that only 5 per cent of the total number have an adequate cost accounting organization. Investigation has shown the great value of this work, not as a means of record, but as a source of knowledge for the proper administration of the work.

The need applies equally in the commercial research laboratory. Here the question of raw materials and machinery accounts need not be considered, but rather the item of labor of chemist and department head is covered under direct expense, and burden or overhead under indirect expense. The cost embraces this direct expense plus the indirect, which includes the official salaries, etc. To this cost a fair percentage of profit must be added, in order to obtain price to be charged the client.

If this system is not used one job or one department will be supporting another, and an ultimate loss of money may result. Where so diversified a work is carried on as in this business the executive, to be successful, must have an accurate idea of what each department is doing. The various departments of a commercial laboratory ordinarily resolve themselves into analytical, research, paper pulp, textile, cement, oil and engineering laboratories.

An effective system must be simple and free from red tape. The executive must work with the accountant in establishing and carrying out the system with this thought in mind.

After the record has been carried on for a period of, say, one year, the data are then available for fixing prices to be charged for analyses. During this time the average costs may be obtained from working time required by different chemists on the same analysis. Future deviations from this average will serve to show up the weak and the strong operators, and awards may be given through praise or even a cash bonus. It is obvious that a skilled chemist saving the company money on each analysis is entitled to substantial reward. Efficiency is then increased by desire for this reward and the man develops a pride in his work.

A laboratory without a cost accounting system is like a ship without a rudder. The executive must know the details of his business. The object of this paper is to arouse the interest of each member in the development of his own business. Once installed he will ask himself, "How did I ever get along without it?"

The paper was commended highly by the members of the section and the author volunteered to help any member who would communicate with him, by giving the benefit of his own experience.

Modern Commercial Explosives—R. L. HILL. The processes of making the commercial explosives were given in outline. The explosive and non-explosive ingredients are made separately and then mixed under proper conditions. The well-known black blasting powder is still popular with the trade. The dynamites are classified as straight dynamite, straight gelatine dynamite, ammonia dynamite and ammonia gelatine dynamite.

The straight and straight gelatine dynamites under the old methods of manufacture are liable to freeze at temperatures as high as 50 deg. F. and the ammonium compound is substituted for the sodium and potassium in the production. Ammonium nitrate compounds are largely used in Europe, but the hygroscopic qualities make it hard to protect from deterioration in damp climates. The protection from this is usually taken care of by the use of a moisture-proof container.

Permissible explosives are used chiefly in coal mine blasting, where danger of ignition of mine gases exists. The substance is compounded with the view of having as little flash or fire with the detonation as possible. The explosion is not entirely devoid of flash, but the amount may be greatly reduced. The powder must have a large deficiency of oxygen, high amount of water content, as in $(\text{NH}_4)_2\text{NO}_3$, and be low in nitroglycerine.

The nitro-starches came into great demand during the war and make a good industrial explosive for some purposes. They have a high order of detonation.

The consumer of explosives is more critical of the product than in perhaps any other business. It is necessary to consider chemical properties from the time raw material arrives at the factory until the charge is planted by him. Careful chemical control is involved in every stage of manufacture. Testing galleries show proof of the finished product. Permissible limits of change or deterioration until put in use must be known. Specifications for the particular article desired should include strength, density, velocity of detonation, sensitiveness of the primer, consistency, water resistance, cold resistance and nature and volume of resulting gases.

Chemical Reagents Received by the Bureau of Chemistry During the War—H. E. BUC. The Bureau began testing samples sent in a great many years before the war and found the products satisfactory until about six years ago, when left-over chemicals began to come on the market. After 1915 the shipments became very unsatisfactory, about 150 analyses out of 1300 showing an excess of impurities. The labels on the bottles were inaccurate as to the contents.

In general the acids and alkalis were permissible and the soluble salts were acceptable, but not of a high degree of purity. The insoluble products were unfit for use.

Report on the Production of Synthetic Organic Chemicals in the Research Laboratory of the Eastman Kodak Co., 1918 and 1919—C. E. K. MEES. The work of commercial preparation of these compounds began in September, 1918, and has continued over a period of eleven months. Great help has been received from the chemists and manufacturers as well as the university laboratories, including the Universities of

Illinois, Missouri and Oklahoma, and the College of Forestry at Syracuse, N. Y. It is the desire of this organization to act as a clearing house for all this class of work. Five hundred and sixty chemicals were included in the plans and of these 348 were undertaken, with this laboratory working on 268 out of the latter quantity.

Chemicals of three degrees of purity were supplied to the trade, Eastman's Best, the highest grade; commercial grade, ordinary synthetic chemicals with impurities marked on the label; and technical chemicals. The last mentioned class was not made in the laboratory, but was purchased in commercial lots from the manufacturers and repacked in small quantities for users requiring it.

The financial statement for the period of 11 months of this work showed a loss of \$17,397, of which \$6000 is depreciation of stock caused by the difference in present market figures and the purchase prices with war-time inflation. As an example of the decreasing loss, the July figures show a total of \$304—manufacturing loss. During this month there was \$747 charged to depreciation and overhead expense. There is a current loss due to explosions incident to the experimental operations and for this reason a profit cannot be shown for several years to come.

A reduction of the loss might be effected by increased production, involving, however, a large outlay for apparatus. As now working this can be done only as demand for product develops. The field of activity could also be narrowed by dropping development work and confining efforts only to chemicals for which there is a paying demand.

The work is exceptionally dangerous and the risk unavoidable, as about 32 new preparations are started per month. New buildings are being erected to house the laboratory so as not to endanger the loss of the Eastman plant through fire or explosion. The author believes the ultimate success of the undertaking is assured if the products of the German chemists are not purchased.

Symposium on Refractories

Dr. MINER resigned the chair to A. V. BLEININGER, who called attention to the many undetermined factors in the manufacture and application of refractories. These materials entering into the construction of furnaces of all sorts must be not only resistant to heat but also to mechanical shocks, heavy pressure and the scouring action of materials under treatment. The paper, "Classification of Refractories," by G. H. BROWN was not presented but was said to contain a review of the different types from the high-grade flint clay brick, the silica and magnesite refractories down to the common fire clay brick.

Work of the Technical Department of the Refractories Manufacturers' Association—R. M. HOWE. During May, 1917, the Manufacturers' Association established a fellowship at the University of Pittsburgh for research work on refractories. A laboratory was equipped and tests commenced on fire brick. Since that time the personnel has increased from one to five investigators and over 50 companies have been served. The organization is self-supporting and its mode of operation is such as to prevent a monopoly of the service by any one company. Some tests have been made on magnesite and silica.

The work has embraced mining selections by drill cores, analyses of same, together with investigations of mixtures and blends made up of brick bats, bauxite, silica, etc. Among other factors considered were temperature operation, water content, abrasive qualities and physical strength. It was found that an increase of water content increased the strength of the brick. Method of manufacture and drying depends on type of clay as regards its contraction characteristics. Performance of brick under service is also a part of the work.

The Selection of Refractories for Industrial Furnaces—W. F. ROCHOW. The chemical composition of a refractory material is not so important as heretofore considered, especially in many cases where the temperature is not of sufficient height to reach the point required for chemical reaction between the walls of the furnace and the material being treated. It is often better to use an acid brick with a basic material, or vice versa. An example of this is the use of silica brick in the glass industry.

Silica brick is found to be 25 per cent better than fire clay for by-product coke ovens due to its high thermal conductivity, mechanical strength and high fusing point. A more uniform temperature is secured in mufles due to the high thermal conductivity. Thermal expansion of silica brick occurs between 230 and 500 deg. C. and the heat must be carefully applied through this range. It is practically eliminated after the first burning. The mechanical strength is good at high temperatures. In arch construction it is insulated with kieselguhr. Long service of a brick in open-hearth furnaces shows four distinct strata with the lime stratum carried to the center of the brick and away from the heat.

Magnesite brick is not strong at high temperatures, and in order to remedy this feature a soft steel band or casing is built around blocks of dead burned magnesite for such work as gas ovens.

Interesting Facts Concerning Refractories in the Iron and Steel Industry—C. E. NESBITT and M. L. BELL. Refractories are an important factor in the successful operations of the iron and steel industries. Good results will obtain if the producer of brick cooperates with the consumer, for the latter should know what the product must stand and the manufacturer must know the limitations of his product.

The range of temperature in the iron furnace varies from 200 deg. C. at the top to 1600 deg. C. at the tuyères. The chemical and physical properties should be known. Test conditions must be more severe than operating demands. Questions are raised by the tests given through the American Society of Testing Materials such as why the life of the same type of brick varies from 2 to 7 years or why converter bottoms last from two to six heats, and some of the individual bricks stand intact in these bottoms, while others are destroyed.

Simple tests should be evolved for use of the consumer so that quantity runs could be made. It has been evidenced, with a variation in temperature from 30 to 1350 deg. C. that the crushing strength is reduced 60 per cent, and that loss in open-hearth roofs have been 20 per cent with 261 heats due to fire cracks. The variation in chemical composition occurs when fumes penetrate the pores in open-hearth work. The

method of manufacture has a pronounced effect on the qualities of clay brick.

Superior Refractories—R. C. PURDY. The vital importance of the electric furnace calls for adequate refractories. The electric industry needs them for high-tension insulators, spark plugs in aircraft, etc. New high-temperature alloys, new glasses, new by-products demand superior refractories. The manufacturer and consumer must co-operate in developing the particular refractory for the special requirement.

As an illustration of refractory failures, fire clay may be taken. It ranges from 100 per cent kaolinite to complex mixtures in composition. The fusion in the brick during manufacture should be carried only to the required point without distortion, and there the heat action should be arrested. This point is largely determined by physical evidence. Melting points are resolved into melting ranges when a mixture of minerals is involved. A 1600 deg. C. brick might be finished at 1000 deg. C.

The essential requirements in superior refractories are heavy loads at high temperatures, no chemical action, constant volume, resistance to abrasion and sudden temperature changes; and these are met by physical strength, high fusibility and low volume changes.

The classification as regards acid, basic or neutral brick is not important. The exceptions are small in number. The future superior refractory may come from fused alumina, carborundum and so-called rare earths providing the cost is not prohibitive. Little bonding material is to be used and then fusible substances or silicate of soda only.

Refractory Problems in the Gas Industry—W. H. FULWEILER and J. H. TAUSSIG. Coal gas retorts operate at 1000-1200 deg. C. in one type, 1400-1500 deg. C., and 1350-1500 deg. C. in another type. The temperature at the top of retorts is about 850 deg. C. The internal surfaces have variation in temperature due to filling with coal at 12-hr. intervals. Both silica and fire brick are used with an expansion of $\frac{3}{8}$ in. per ft. above 300 deg. C. and $\frac{1}{16}$ in. per ft. gradually to 1100 deg. C., respectively.

These expansions make the problem of construction a difficult one. Cast iron supports and double arches must be allowed for. The various parts are kept in line and slip joints are provided. A mixture of 96 per cent silica and $1\frac{1}{2}$ to 2 per cent lime is used in one type cement, and 55 per cent silica and 45 per cent alumina in another bonding material.

Water gas is made in three steel brick-lined shells connected in series, brick checkerwork filling in the last two. The first or generator shell operates at a temperature of 1700 deg. C. in the highest part, where fine coke particles form a clinker on the sides. Steam is admitted at the bottom. The chemical effect of the clinker is not important at the top, but it must be frequently pried away from the brickwork, causing abrasion. Dropping to the floor of the generator, it reaches a high temperature (1100 to 1700 deg. C.), and chemically attacks the floor and lower wall.

Fire brick is used in the second and third shells because silica will not stand the sudden temperature changes caused by dosing every 4 min. with cold oil.

Zircon and carborundum bricks stand up well for gas work, but the cost is thirty times that of other grades. The better cements used in construction, and consisting of brick binder with a small amount of fusi-

ble material, are hard for the mason to work, because of poor spreading qualities. These features of expense must be weighed against the final improvement to determine the advisability of their adoption.

Symposium on Annual Patent Renewal Fees with the Division of Pharmaceutical Chemistry and Section of Dye Industry

The division met on Friday morning with a number of the members of Pharmaceutical and Dye Divisions present and Dr. MINER vacated the chair for E. J. PRINDLE. The members were asked to confine their remarks strictly to the subject at hand, as time did not permit the discussion of the patent situation in general.

Dr. HESSE had previously proposed by letter that taxes be imposed on U. S. patents, beginning with the eighth year. Quotation of part of his letter is as follows:

"Our patent system is founded on the constitutional provision that 'Congress shall have power to promote the progress of science and the useful arts, by securing for limited times to authors and inventors, the exclusive rights to their writings and discoveries.' It seems to me only fair to assume, therefore, that Congress is not to grant these exclusive rights if by so doing 'progress of science and useful arts' is needlessly impeded or obstructed.

"An inventor who allows his patent to lie idle transgresses the spirit underlying the patent system. He is reserving to himself a field of endeavor which he has agreed to exploit and is not exploiting, and by his reservation he prevents the exploitation by others and thus retards progress.

"A possible remedy for this might be a low annual tax, say from \$15 to \$25, or some other sum not high enough to stand in the way of any inventions giving any reasonable promise of remuneration, yet high enough to make it appear unprofitable to retain reservations which inventors are either unwilling, unable or incompetent to develop.

"When a German inventor forfeits his German patent he thereby opens that field for development and exploitation by Germans in Germany, but because he does not also at the same time relinquish his corresponding rights in the United States, we are barred by our own laws and by our own acts from enjoying a liberty of action and a freedom of invention which the Germans enjoy. A dead German patent, therefore, still lives and rules in the United States.

"I am of the opinion that such a tax system as here proposed would effectively remove much of the grip which foreign and especially German patent inventors have on our domestic industry, and would also relieve us of the congestion due to patents of our own citizens which are not exploited or serve no useful purpose and to some extent, at any rate, of that class of domestic patentees designated, more or less unjustly perhaps, as patent sharks, trailers or pirates."

Mr. PRINDLE stated the following points in regard to Dr. HESSE's proposal should be considered:

1. Is the principle of patent taxation a sound one?
2. Would taxes restrict pirates?
3. Would taxes restrict the poor inventor?
4. Would they liberate patents from corporation control?

5. Would a new field be opened up?
6. Would held patents be forfeited?
7. Should patents be free from taxation the first seven years, and if not for what period?
8. What size of fee should be charged and should it remain stationary or increase?

Dr. L. H. BAEKELAND. The subject has been debated before. The system of patent laws in the United States is theoretically the most liberal of all countries and has been held up as a model one. There is a difference between theory and practice, however, and it is really intricate and complicated, to the detriment of the inventor.

The purpose of taxation is to eliminate so-called paper patents, some of which are a hindrance. The tax in European countries is a pretext at revenue collection. Under their systems a good many patents lapse and hardship is worked on the poor and honest inventor. The large companies gladly pay these renewal fees and the lapsed patents are largely those owned by individuals, the very people who need encouragement. Paper patents are eliminated, it is true, but the beginner is penalized.

The recent hearings in Washington on the patent situation are full of minor details, detracting from the fundamental changes really involved in the proposed House bills. They should forget these unimportant features and stick to main issues.

Dr. C. E. K. MEES, Eastman Kodak Co., presenting a paper written by Mr. STINCHFIELD, the company's patent attorney. If we examine fundamentals we will see that the principal object of the patent grant is to promote public interest in invention. The Government gives the inventor a limited monopoly in exchange for the free public use of this discovery later. The fees charged are only to cover the expenses of the Patent Office, and taxes should not be added.

The proposed taxation would not be equitable because the Government cannot cancel a contract with the inventor where his discovery has been previously revealed. His secret cannot be recalled.

No good will be accomplished by elimination of paper patents, as they harm nobody. It is like shooting a corpse. The live patents would not be allowed to lapse. Incentive to invention would be smothered. The tax would not be strong enough to help the situation. The forfeiting of unworked patents in Europe also acts unfairly, where they are immediately grabbed, and in cases of old patents becoming suddenly valuable the originator reaps no reward for his ideas.

The public secures something for nothing. Taxes are an especially heavy burden on the poor inventor and small business concern. If more fees must be charged, let it be done with the view of getting an adequate Patent Office organization in this country.

Dr. L. V. REDMAN. A system of fees is not satisfactory, if we assume our present patent principles are sound, i.e., that the monopoly given will stimulate invention and discovery. The renewal fee proposed would be justified if it eliminated the existing evils, but it would not do so. What applies in foreign countries does not apply here, due to differences in conditions. As a measure of reciprocity it would not work.

We cannot expect to correct abuses by taxing legitimate corporations for practicing their patents. Is the method of taking out and holding patents an abuse?

A patent is fundamentally intended to be a monopoly. These contingent patents are not an abuse, because they are taken out to provide protection against parallel ideas intended to destroy the monopoly enjoyed by the basic patent. Their existence saves endless litigation.

The accusation that corporations take out contingent patents and withhold using the improvement is an assertion and not a proved fact. They must manufacture the best possible product or competition would spring up. If the good ideas were suppressed, the company would decay.

The patent pirate ties up new industries by taking out accessory patents to complicate the original claims without any intent to manufacture on his own account. He should be eliminated. Accessory patents should be allowed to the original inventor. There should be no taxes for revenue only, i.e., on working patents.

The chairman asked Mr. REDMAN if he thought such discrimination could be made and he replied that it could be by providing that no tax be placed on basic patents. The chairman called attention to the impossibility of reading the inventor's mind or intentions. Mr. REDMAN replied it was not hard to point out the pirate practically, but as to legal possibilities he could not say.

Mr. J. M. WEISS stated that true commercial patents would not be harmed by the small fees proposed and asked if Dr. BAEKELAND might not be mistaken in his statement that the majority of lapsed patents in European countries were those of poor inventors. He further stated that the taxes would clear the field of old patents which unfairly restrict development, because at the time they were taken out the inventor was not considering the field now affected.

Dr. BAEKELAND replied that he had personal acquaintance with a great many poor inventors both here and in Europe to whom the so-called small fee was an important item, often causing the loss of patents.

Mr. E. J. PRINDLE temporarily relinquished the chair to speak in substance as follows:

"Does the tax promote or deter the purpose for which the patent laws were enacted? Its purpose was to benefit the public by inducing inventors to reveal their secret by giving them a monopoly for a limited time and then it belonged to the public, adding to the treasury of public knowledge.

"Ours was the first practical patent system and ability to invent was rapidly developed in the people. The great wealth of this country is based largely on this fact. This inventive ability is not an inherent trait in our people, the majority of whom are descended from European stock, but is a result of our patent system. We should therefore be careful to do nothing to impair this situation.

"I wish to state that I am quite as much opposed to Germany's peaceful penetration, and quite as desirous of seeing her prevented from using unfair methods as Dr. HESSE can be. We should, however, consider any such proposal in the light of all its reactions and its effectiveness to accomplish that purpose.

"Any amendment to our patent law should conform to its fundamental purpose, which is to secure the production of inventions. The assumption and the fact are that inventions would ordinarily not be produced, if it were not for the inducements of the monopoly provided by the patent system.

"The path which the inventor must travel before

he can reap any return is already so difficult that many doubt that it is worth while to make inventions.

"The patent committee of the National Research Council has taken the position that the incentive of the inventor should be increased rather than diminished, and its report to that effect has been approved by this society, and by many scientific societies, and by several of the large trade organizations.

"The Supreme Court of the United States has decided that the patent law does not require the inventor to work his invention.

"The effect of the annual renewal would be to impose a burden which many individuals and corporations would hesitate to face. Many of the most important inventions have been made by comparatively poor inventors on their own financial resources, and if, after having gotten their patents, they would still have to pay a series of annual taxes totaling a possible \$550, and which in no way aided the exploitation of the invention, many of them would undoubtedly not attempt to make these inventions. The possibility of overlooking to pay the renewal fees, and thus losing all the time and money put into the invention and patent and all hope of future return, would act as a deterrent not only to the inventor but to any purchaser as well.

"Annual renewal fees would work a discrimination in favor of the rich man and the corporation against the average inventor.

"Furthermore, I do not believe that the imposition of annual taxes upon our patents would materially alter the German advantage under our patents. If a German-owned American patent were valuable in suppressing competition here, the Germans would unhesitatingly pay the renewal fees, even if they were much larger than the proposed taxes. If, on the other hand, the patent were so unimportant that the Germans would permit it to lapse for failure to pay the renewal fee, it would be of no advantage to us to be free to use it, for we should not want to use it.

"To be worth while a remedy must be one which will not only effectively check the Germans, but one which will not at the same time injure us—and more than them. The proposed remedy is not such a one.

Mr. HOLMES of the U. S. Patent Office was called upon and agreed with Mr. PRINDLE'S remarks.

Dr. T. HART ANDERSON telegraphed that he did not advocate a change, but was in favor of taxing foreign patentees as a matter of reciprocity. The taxes would probably be paid by them, however, on important patents.

Dr. J. M. FRANCIS wrote he was at a loss as to how to consider Dr. Hesse's letter. A tremendous stake is involved and our laws are good. A change might involve a terrible loss. The principles are good, but the remedy of taxation is poor, being a serious handicap to the young inventor.

Prof. ELIHU THOMPSON wrote he was opposed to the idea of fees, because the system of the Patent Office would be complicated by their collection. When an inventor is ahead of his time he should receive his reward when the development of the field calls for the use of his patent. The duration of time required for development of a basic idea after its first inception is sometimes very long, as in the case of large apparatus, and the reward should not be lost to the inventor.

Dr. W. R. WHITNEY of the General Electric Co. wrote that he would attempt to care specially for the ques-

tion of the unfair standing of foreign inventors rather than reduce the favors extended to the American inventors. He declared that everything should be done to encourage young men to train themselves to be inventors.

Dr. A. D. LITTLE wrote that the fees in Europe were an unmitigated nuisance and the system should not be adopted.

E. A. HILL of the U. S. Patent Office wrote that the officials in the Patent Office organization agreed the burden of proof rests on those who want a change in the laws. Why experiment with the unknown? He is opposed to the tax, but recommends support of patent bills now before Congress.

Dr. HARLAN S. MINER proposed a resolution recommending to Congress that House bills Nos. 5011, 7010 and 5012 of the 66th Congress, first session, relating to patents and originally introduced through the patent committee of the National Research Council, be passed by that body. The resolution was unanimously carried. It was then suggested that each member of the A. C. S. write personal letters to his own Representative and Senators and also to John I. Nolan asking that the bills in question be favorably voted upon.

Continuation of Papers

Tensile Strength of Glue—G. HOPP. Viscosity and jelly strength have been used in testing glue, but tensile strength and stretch when applied are what is really required. The method of gluing boards and then pulling has not been satisfactory, since results obtained by this method were not uniform.

The new tests made consisted in molding the glue in strips, placing on a tin or aluminum screen to dry, and machining down to dimension required with a tolerance of about 0.001 in. Samples were then pulled in a 500-kg. machine with the jaws carefully aligned. Some of the results were as follows:

Glue	Stretch, Per Cent	Tensile Strength, Lb.
No. 1.....	4½	13,240
No. 2.....	2	8,520
No. 3.....	2	7,690
No. 4.....	3½	11,570

These results are the average of a number of samples in each particular instance and the variation from the average was 1 to 3 per cent. The samples were kept under standard condition of temperature and humidity (75 deg. F. and 65 per cent humidity) until pulled, at room temperature. Complete test requires a maximum of five days.

Carbon Black—Its Properties and Uses—G. ST. J. PERROTT. An investigation of the carbon black industry has been undertaken by the Bureau of Mines as a result of economic issues brought up during the war. In the present process of manufacture carbon black is made by burning natural gas with an insufficient supply of air for complete combustion, collecting the liberated carbon on a metal surface. This process produces from ½ to 2 lb. per 1000 cu.ft. of gas or 1.5 to 6.5 per cent of the total carbon in the gas.

The process at first sight seems wasteful, but examination shows it is at any rate the only one in practical operation that produces carbon black suitable for the ink trade and rubber industry consumers, whose combined use is over 30,000,000 lb. annually. The whole situation appears to necessitate thorough investigation before any opinion can be given as to the wastefulness of the present process.

Accordingly the industry has been studied as to methods of manufacture and properties and uses of the finished product. Plants in Louisiana, Oklahoma and West Virginia have been investigated by Bureau engineers. Other processes of making carbon black have been investigated. The uses of carbon black have been studied with the idea of determining the properties of the product which users of carbon black demand and with an attempt at designating in which of these uses carbon black is essential and in which a substitute material might be employed. Microscopic and chemical analysis of a number of blacks has been made and test methods studied with a view to finding the reason for the very different behavior exhibited by different blacks, particularly as applied to the ink trade.

Adherent Rust as an Accelerator in the Corrosion of Iron and Steel—W. D. RICHARDSON. The experiments on which this paper is based lasted over a period of 1030 days and results were tabulated. If we look on corrosion as an electrolytic phenomenon, we then must consider iron as the anodes and the cathodes to be embraced in both the other substances in the metal, such as carbon and copper, and also outside substances lying on the surface of the metal. These latter take the form of oxygen, CO_2 , oil, rust, etc.

Conclusion is that the dominant substance in the corrosion is oxygen. Hydrogen ions also play a part. Depolarizers consist of the rust and mill scale, the latter disappearing and leaving the rust to do the work. Clean iron surface is very sensitive to corrosion and the substance on its surface determines the speed with which it starts. Highly polished surfaces, being a coating of the pure metal smoothly spread over the pores and free from presence of internal impurities to act as cathodes, start to corrode very slowly. When clean without polish ferrite and carbon are present to start immediate electrolytic action.

Mill scale or rust over the surface stops the course of the corrosion. Under the rust is usually found a black film (Fe_3O_4), which assists in retarding the action. Oil or other substance acts in the same way.

Cast-iron plates 6 in. square and $\frac{1}{2}$ in. thick, and steel plates $\frac{1}{16}$ in. thick were used in the tests. These were placed in distilled water at rest, in distilled water with air agitation, in 10 per cent brine solution at rest and a 10 per cent brine solution with air agitation. In some cases the plates were removed and dried at intervals.

The losses by rust in brine were less than in distilled water because a smooth coating was soon formed which stopped further action, while in distilled water the rust was porous and action continued. Cast metals corrode less rapidly than steel metals due to nature of rust formed.

In no instance does the chemical composition of the metal influence the starting of corrosion, which really depends on some external substance, undoubtedly oxygen. The rate of corrosion after the start is made depends entirely on physical structure of rust formed.

Some Properties of Commercial Silicate of Soda—J. G. VAIL. Ordinary window glass is made from sand, soda and lime, melted together in a furnace. If we leave out the lime and increase the proportion of soda, the furnace yields a product, silicate of soda, which looks exactly like glass. This may be dissolved in water by the aid of special apparatus. The solution is the syrupy liquid familiar to almost everyone as

water-glass. It has long been used for preserving eggs. More lately it has been found to possess many of the properties of glue. It is a strong adhesive. It sets rapidly. It cannot mold or spoil, and it is very much cheaper than glue.

As wood from our forests becomes more and more scarce, paper boxes, instead of wooden ones, are being used for shipping containers, but paper is neither thick enough nor strong enough to build boxes for shipping canned goods, shoes, soap, or the thousand and one things that are carried every day by the railroads. So the sheets of paper have to be pasted together, three, four and sometimes five-ply, to make a strong, tough product. For this the mineral adhesive, silicate of soda, is universally employed. It sticks so quickly that the rolls of paper can pass through the pasting machine at 150 ft. per min., and the combined board can be cut into sheets and fashioned into boxes without waiting for the adhesive to dry. After filling, the boxes are sealed with silicate of soda.

The box industry is growing, but there are a great many other industrial uses for a material to stick things together. Silicate of soda, the mineral adhesive, is the cheapest and the best for many of these purposes. It was hardly known for adhesive purposes 10 years ago, and scientific study of its properties and how to make and use it are constantly showing more ways to apply it. Animal and vegetable products which can be used for food are thus conserved for their rightful use. This is genuine economy.

The Leaching of Zinc Chloride From Treated Wood—ERNEST BATEMAN. This paper covered a large number of tests made on various woods by treating with 1 per cent, 3 per cent and 5 per cent solutions of zinc chloride, allowing to dry 28 days and testing. Results show the Cl radical comes out, leaving an excess of zinc. Basic zinc salts do not prevent decay, the Cl radical must be present to form ZnCl_2 , or the wood is not protected from decay. The ZnCl_2 treated tie can be used in climates having not over 40 in. of rainfall per annum.

In addition to those outlined above the remainder of the 27 papers were read. These papers were of equal merit in the work covered. Each author showed long preparation and careful thought on his particular assignment. With such continued application of the individual member and a co-ordination of these efforts by the able leaders, one may well hesitate to predict the high state at which the industry will arrive during the coming decade.

Excursions

On Thursday afternoon seventeen of the representative plants of Philadelphia opened their doors to the convention. The bleach department of the Dill & Collins paper mills is described elsewhere in this issue. An account of the trip through the Atlantic Refinery, Barrett's, Electric Storage Battery, Foerderer, Warner and Welsbach plants will be given in the next issue.

For those wishing to avail themselves of the historical features offered in the Philadelphia vicinity, excursions were arranged to visit the old Colonial Capitol buildings containing the Liberty Bell and many objects of interest. Valley Forge, the winter camp of Washington's army in its final struggle before victory over Cornwallis, was visited by those who had seen the national shrines located in the city.

Program of Exposition Week

Fifth National Exposition of Chemical Industries—American Electrochemical Society—American Institute of Mining & Metallurgical Engineers—Technical Association of the Pulp & Paper Industry—American Ceramic Society—American Steel Treaters' Society

Fifth National Exposition of Chemical Industries

Coliseum and First Regt. Armory

Monday, Sept. 22

12 M.

Opening of Exposition.

2 P.M.

Meeting American Institute Mining & Metallurgical Engineers at Congress Hotel.

8 P.M.

Opening addresses at Chemical Exposition Auditorium.

Gov. FRANK O. LOWDEN of Illinois will make the address of welcome.

CHARLES H. HERTY, chairman of advisory committee, will respond.

JOHN W. O'LEARY, president Metal Trades Association of Chicago, "The Relation of the Chemist to the Manufacturer."

HERBERT H. DOW, "How Long Does It Take to Develop a Laboratory Process Into a Dividend?"

9 P.M.

Motion pictures in Chemical Exposition Auditorium.

Tuesday, Sept. 23

8 A.M.

Departure of members of the American Institute Mining & Metallurgical Engineers and American Electrochemical Society making excursion to steel mills at Gary, Ind.

2 P.M.

Symposium on "America's Case in Chemistry," at Chemical Exposition Auditorium, with ELLWOOD HENDRICK, president Chemists' Club and consulting editor CHEM & MET. ENG., as chairman.

"Dyestuffs," by J. MERRITT MATTHEWS, editor *Color Trade Journal*.

"Chemical Porcelain," by HERMAN S. COORS, of Herold China & Pottery Co.

"Laboratory Supplies; Lamp-Blown Glassware and General Apparatus," by C. G. FISCHER, of Scientific Materials Co.

"Glassware," E. C. SULLIVAN, of the Corning Glass Works.

"Laboratory Supplies; Instruments of Precision," by J. M. ROBERTS, secretary Apparatus Makers' Association of U. S.

"Optical Glass," by HARVEY N. OTT, of Spencer Lens Co.

8 P.M.

Motion pictures in Chemical Exposition Auditorium: "History and Utilization of Coal."

Joint Technical Meeting of American Institute of Mining & Metallurgical Engineers and American Electrochemical Society, on subject of "Iron and Steel," at Congress Hotel.

Wednesday, Sept. 24

10 A.M.

Meeting at Chemical Exposition of American Electrochemical Society for reading and discussion of papers.

Registration and meeting at Chemical Exposition of Technical Association of Pulp & Paper Industry in Officers Room, First Regiment Armory.

Address of welcome.

Opening address by president.

Report of executive committee.

Report of secretary-treasurer.

Reports by standing committees.

Meeting at Chemical Exposition of American Ceramic Society.

2 P.M.

Joint technical session American Electrochemical Society with American Institute Mining & Metallurgical Engineers at Chemical Exposition Auditorium.

2:30 P.M.

Meeting at Chemical Exposition of American Ceramic Society resumed.

3:30 P.M.

Meeting at Chemical Exposition of Technical Association of Pulp & Paper Industry resumed.

6:30 P.M.

Dinner of Technical Association of Pulp & Paper Industry at Union League Club.

8 P.M.

Motion pictures in Chemical Exposition Auditorium.

Thursday, Sept. 25

9:30 A.M.

Meeting at Chemical Exposition of Technical Association of Pulp & Paper Industry; general business meeting.

10 A.M.

Meeting of American Electrochemical Society jointly with American Institute of Mining & Metallurgical Engineers. Symposium on "Pyrometry" at Congress Hotel.

12 M.

Technical Association Pulp & Paper Industry adjournment for luncheon at, and as guests of, Sears, Roebuck & Co., to be followed by visit to the paper mill plant.

2 P.M.

Meeting at Chemical Exposition Auditorium.

"The Organization and Plans of the National Re-

search Council With Special Reference to the Industries," H. E. HOWE, National Research Council.

"Fields for Industrial Development, Canadian National Railways," PRICE GREEN, Industrial Commissioner, Canadian National Railways.

"Filtration," HENRY B. FABER, Industrial Filtration Corp.

"Destructive Distillation Bituminous Material with Reduced Vapor Tension and Complete Temperature Control," THOMAS W. PRITCHARD, vice-president Fuel Products Corp.

4 P.M.

Committee meetings Technical Association Pulp & Paper Industry at Chemical Exposition.

8 P.M.

Motion pictures at Chemical Exposition.

8 P.M.

American Electrochemical Society smoker at Congress Hotel.

8:30 P.M.

Technical Association Pulp & Paper Industry smoker.

Friday, Sept. 26

Technical Association Pulp & Paper Industry will visit Forest Products Laboratory at Madison, Wis.

9:30 A.M.

Meeting of American Electrochemical Society at Chemical Exposition Auditorium. Subject: Symposium on "Catalysis."

2 P.M.

Meeting of American Electrochemical Society resumed.

8 P.M.

Motion pictures. JAM HANDY, vice-president Bray Studios, address, "Art Exposes the Invisible in Chemistry," during the showing of special films.

"Natural Resources on C. N. Ry." PRICE GREEN, Industrial Commissioner of Canadian National Railways, address during showing stereopticon and motion pictures.

8 P.M.

Award of Willard Gibbs Medal to Prof. W. A. NOYES, University of Illinois, by Chicago Section of American Chemical Society.

Saturday, Sept. 27

9:30 A.M.

Meeting at Chemical Exposition headquarters of Technical Association of Pulp & Paper Industry for adjourned business session in auditorium.

AFTERNOON

Technical Association Pulp & Paper Industry official visits of inspection to exhibits at Chemical Exposition.

2 P.M.

Meeting at Chemical Exposition Auditorium. Symposium on Safety in Plant and Mine under chairmanship of M. F. LEOPOLD, safety engineer, U. S. Bureau of Mines.

8 P.M.

Motion pictures, depicting safety work in the plant and mine, by courtesy of U. S. Bureau of Mines.

American Electrochemical Society

Monday, Sept. 22

6 P.M.

Registration begins at headquarters, Congress Hotel. Society headquarters at Exposition in booths 235-236 on balcony of Coliseum.

Tuesday, Sept. 23

All-day excursion by boat with the American Institute of Mining & Metallurgical Engineers to Gary, Indiana, and trip through the United States Steel Co. plant. Details about tickets at the registration desk.

10 A.M.

Meeting of Directors.

12 M.

Luncheon at Steel plant.

1:30 P.M.

Inspection of United States Steel Co's plant. Joint technical session with the A. I. M. & M. E. General subject: "Iron and Steel."

8 P.M.

Joint technical session with the A. I. M. & M. E. at the Congress Hotel (continued).

Wednesday, Sept. 24

10 A.M.

Reading and discussion of papers at Chemical Exposition Auditorium.

"Manganin," M. A. HUNTER and J. W. BACON.

"The Activation of Carbon," N. K. CHANEY.

"Depreciation in Small Dry Cells With Age," A. J. HELFRECHT.

"The Effect of Amalgamation Upon the Single Potential of Aluminum," LOUIS KAHLENBERG and JOHN A. MONTGOMERY.

"The Effect of Amalgamation Upon the Single Potential of the Binary Alloys of Al With Cu, Zn and Ni," LOUIS KAHLENBERG and JOHN A. MONTGOMERY.

2 P.M.

Joint technical session with the A. I. M. & M. E. at Chemical Exposition Auditorium. General subject: "Ferrous and Non-Ferrous Metallurgy."

"Radiant Resistor Furnace," F. A. J. FITZGERALD.

"Electric Heat in the Typewriter Industry," A. M. CLARK.

"Electric Furnace for Experimental Work," F. A. J. FITZGERALD.

"A Square Deal for the Electric Furnace," H. G. WEIDENTHAL.

(See also papers for this session on the program of the A. I. M. & M. E.)

EVENING

Inspection of the electric furnace exhibits at the Exposition.

8 P.M.

Motion pictures in Exposition auditorium.

Thursday, Sept. 25

10 A.M.

Joint technical session with A. I. M. & M. E. Symposium on Pyrometry at Congress Hotel.

2:30 P.M.

Continuation of joint session.

8 P.M.

Complimentary smoker at Congress Hotel, tickets of admission to be obtained from the registrar.

Friday, Sept. 26

Symposium on Catalysis at the Chemical Exposition Auditorium.

"Some Problems in Contact Catalysis," W. D. BANCROFT.

"Further Problems in Contact Catalysis," H. S. TAYLOR.

"The Thermal Problem in Organic Contact Catalysis," W. J. HUFF.

"Thermal Problem in the Contact Process of Sulphuric Acid Manufacture," F. C. ZEISBERG.

"Modern Theories of Matter and the Problem of Catalysis," E. K. RIDEAL.

2:30 P.M.

Meeting at Exposition Auditorium.

"Demonstration of Manufacture of Fluorine," F. C. MATHER and BURR HUMISTON.

"Factors Governing the Structure of Electrodeposited Metals," WILLIAM BLUM.

"Lead Plating From Fluoborate Solutions," WILLIAM BLUM, F. J. LISCOMB, ZALIA JENKS and W. E. BAILY.

"Commercial Possibilities in Electrochemical Production of Organic Compounds," C. J. THATCHER.

American Institute of Mining and Metallurgical Engineers

Monday, Sept. 22

MORNING

Registration begins at headquarters, Congress Hotel.

11 A.M.

Technical Sessions:

1. Session on Non-Ferrous Metallurgy and Metallography.

The papers will be read here by title only to afford opportunity for discussion when presented at the Philadelphia meeting of the Institute of Metals Division.

2. Session on Coal and Gas.

2 P.M.

Technical Sessions:

1. Session on Coal and Gas.

2. Session on Geology.

3. Session on Milling.

4. Session on Industrial Organization.

EVENING

Smoker.

Tuesday, Sept. 23

MORNING AND AFTERNOON

Excursion by boat with the American Electrochemical Society to Gary, Ind., and trip through the United States Steel Co. plant. During the afternoon upon the return trip, on the boat, technical session on Iron and Steel, jointly with American Electrochemical Society.

"Blast-Furnace Refractories," RAYMOND M. HOWE.

"Effervescing Steel," HENRY D. HIBBARD.

"Aircraft Steels," ALBERT SAUVEUR.

"Determining Gases in Steel and the Deoxidation of Steel," J. R. CAIN.

"Effect of Time and Low Temperature on Physical Properties of Medium-Carbon Steel," G. A. REINHARDT and H. L. CUTLER.

"Erosion Tests of Rifle Barrels," A. E. BELLIS.

"Metallography of Rifle-Barrel Steel," G. F. BUTTERWORTH.

8 P.M.

Session on Iron and Steel, jointly with American Electrochemical Society (continued):

"Industries of the Chicago District," T. W. ROBINSON, lantern slides, etc.

"Manufacture of Steel Rails," ROBERT W. HUNT.

"240-inch Plate Mill," C. L. HUSTON.

8 P.M.

Session on Oil:

"Irvine Oil District, Kentucky," STUART ST. CLAIR.

"Petroliferous Provinces," E. G. WOODRUFF.

"Investigations Concerning Oil-Water Emulsion," A. W. MCCOY, H. R. SHIDEL and E. A. TRAGER.

"Essential Factors in the Valuation of Oil Properties," CARL H. BEAL.

"Application of Law of Equal Expectations to Oil Production in California," CARL H. BEAL and E. D. NOLAN.

"Value of American Oil Shales," CHARLES BASKERVILLE.

Wednesday, Sept. 24

10 A.M.

Technical Sessions:

1. Session on Iron and Steel:

"Cooling Properties of Technical Quenching Liquids," N. B. PILLING and T. D. LYNCH.

"Differential Crystallization in Cast-Steel Runner," FRANCIS B. FOLEY.

"Manufacture and Properties of Light Wall Structural Tubing," H. J. FRENCH.

"Oxygen in Cast Iron and Its Application," WILFORD L. STORK.

"Graphitization of White Cast Iron Upon Annealing," PAUL D. MERICA and L. J. GUREVICH.

"Experimental Data Obtained on Charpy Impact Machine," F. C. LANGENBERG.

"Heat Treatment of Cast Steel," JOHN H. HALL, ARVID E. NISSON and KNOX TAYLOR.

2. Mining and Local Resources:

"Winconsin Zinc District," W. F. BOERICKE and T. H. GARNET.

"Mineral Resources of the La Salle District," J. A. EDE.

"New Angles to the Apex Law," JOHN A. SHELTON.

"Mining Methods of Alaska Gastineau Mining Co.,"
G. T. JACKSON.

"Tunnel Driving at Copper Mountain, B. C.," (Columbia Section Paper), OSCAR LACHMUND.

"Geology and Mining Methods at Pilares Mine,"
ALFRED WANTKE, W. ROGERS WADE.

"Wedging Diamond-drill Holes," O. HALL and V. P. ROW.

3. Session on Sulphur in Coal:

"Geographic Distribution of Sulphur in the West Virginia Coal Beds," I. C. WHITE.

"Occurrence and Origin of Finely Desseminated Sulphur Compounds in Coal," RIEINHARDT THIESSEN.

"Mechanical Separation of Sulphur Minerals From Coal," J. R. CAMPBELL.

"Sulphur in Coal—Geological Aspects," GEORGE H. ASHLEY.

"Forms in Which Sulphur Occurs in Coal," A. R. POWELL.

"Effect of Sulphur in Coal Used in Ceramic Industries," C. W. PARMELEE.

2 P.M.

Technical Sessions:

1. Session on Non-Ferrous Metallurgy, jointly with American Electrochemical Society at Chemical Exposition Auditorium:

"Electric-Resistance Furnace of Large Capacity for Zinc Ores," CHARLES H. FULTON.

"Water and Chlorides in Cement Copper," EDWARD KELLER.

"Chemical and Electrochemical Problems Involved in the New Cornelia Copper Co.'s Leaching Process," HENRY S. MACKAY.

"Electrolytic Zinc," C. A. HANSEN.

"Treating Antimony Ores," GEORGE P. HULST.

2. Session on Sulphur in Coal:

"Removal of Sulphur From Illuminating Gas," W. W. ODELL and W. A. DUNKLEY.

"Low Sulphur in Coal," H. M. and T. M. CHANCE.

"Low-Sulphur Coals of Kentucky," WILLARD R. JILLSON.

"Low-Sulphur Coal in Illinois," GILBERT H. CADY.

"Sulphur in the Coking Process," S. W. PARR.

"Commercial Recovery of Pyrite from Coal," S. H. DAVIS.

"Sulphur in Producer Gas," FREDERICK CRABTREE and A. R. POWELL.

3. Session on Pyrometry With Special Reference to Iron and Steel Metallurgy:

Report of the Pyrometer Committee of National Research Council, George K. Burgess.

"Pyrometry in Blast-Furnace Work," P. H. ROYSTER and T. L. JOSEPH.

"Pyrometry and Steel Manufacture," A. H. MILLER.

"Electric Open Hearth and Bessemer Steel Temperatures," F. E. BASH.

"Some Thermal Relations in the Treatment of Steel," CHARLES F. BRUSH.

"Pyrometry in the Tool Manufacturing Industry," J. V. EMMONS.

"Forging Temperatures and Rate of Heating and Cooling of Large Ingots," F. E. BASH.

Evening

Banquet at Congress Hotel.

Thursday, Sept. 25

10 A.M.

Optional excursion to De Pue, Ill., by train for inspection of zinc smelters, cement works and coal mines.

Trip to Starved Rock and points of historical interest.

10 A.M. and 2 P.M.

Technical meeting, subject: Symposium on Pyrometry, jointly with American Electrochemical Society.

"Temperature," J. S. AMES.

"Standard Scale of Temperature," C. W. WADNER, E. F. MUELLER and PAUL D. FOOTE.

"Metals for Pyrometer Standardization," C. W. WADNER and GEORGE K. BURGESS.

"Fundamentals of Pyrometry," C. E. MENDENHALL.

"Thermo-electric Pyrometry," PAUL D. FOOTE, T. R. HARRISON and C. O. FAIRCHILD.

"Potentiometers for Thermo-element Work," WALTER P. WHITE.

"Self-Checking Galvanometer Pyrometer," H. F. PORTER.

"Some Factors Affecting the Use of Base-Metal Thermocouples," O. L. KOWALKE.

"Curves and Tables to Represent the Relation Between Thermal E.M.F. and Temperature," L. H. ADAMS.

"Reference Standard for Base-Metal Thermocouples," N. E. BONN.

"Alloys Suitable for Thermocouples and Base-Metal Thermo-electric Practice," J. M. LOHR.

"Recent Improvements in Pyrometry," R. P. BROWN.

"Automatic Correction for Temperature of Cold Junctions," F. WUNSCHE.

"A Hot Wire Anemometer With Thermocouple," T. S. TAYLOR.

"Porcelain for Pyrometric Purposes," F. H. RIDDLE.

"Pyrometer Porcelain and Refractories," R. W. NEWCOMB.

"Porcelain Pyrometer Protecting Tubes," F. A. HARVEY.

"Porcelain Tubes for Thermocouples," R. B. LINCOLN.

"Melting Point for Refractory Materials," LEO I. DANA.

"High Temperature Scale and Its Application in the Measurement of True Brightness and Color Temperature," EDWARD P. HYDE.

"Theory and Accuracy in Optical Pyrometry," W. E. FORSYTHE.

"Optical and Radiation Pyrometry," PAUL D. FOOTE and C. O. FAIRCHILD.

"Industrial Application of the Disappearing-Filament Type of Optical Pyrometers," F. E. BASH.

"Use of the Optical Pyrometer for Control of Optical-Glass Furnaces," C. N. FENNER.

"Emissive Powers and Temperatures of Non-Black Bodies," A. G. WORTHING.

"Recording Thermocouple Pyrometers," LEO BEHR.

"Recording Pyrometry," C. O. FAIRCHILD and PAUL D. FOOTE.

"A Remote Control Valve Operating Mechanism for Hand or Automatic Control," R. W. NEWCOMB and C. ENGLEHARD.

"High Temperature Control," C. O. FAIRCHILD and PAUL D. FOOTE.

"Resistance Thermometry," F. W. ROBINSON.

"Tin an Ideal Pyrometric Material," E. F. NORTHRUP.

"Resistance Thermometry for Industrial Use,"

CHARLES P. FREY.

"Temperature Measurement in Optical Glass Annealing Furnaces," E. D. WILLIAMSON and H. S. ROBERTS.

"Annealing of Glass," A. Q. TOOL and J. VALASEK.

"Pyrometry Applied to Bottle-Glass Manufacture,"

R. L. FRINK.

"Pyrometry in the Manufacture of Optical Glass,"

ALBERT J. WOLCOTT.

"Pyrometry as Applied to the Manufacture of Optical Glass," CARL W. KEUFFEL.

"Pyrometric Shortcomings in Glass-House Practice," W. M. CLARK and CHARLES D. SPENCER.

"Temperature in the Manufacture of Pottery," F. K. PENCE.

"Pyrometry in the Chemical Industry as Applied to Gas Mask Manufacture," K. MARSH.

"Application of Pyrometry to the Ceramic Industries," C. B. THWING.

"Pyrometry in Rotary Portland Cement Kilns," by LEO I. DANA and C. O. FAIRCHILD.

"Application of Pyrometers to Ceramic Industry," JOHN P. GOHEEN.

"Temperatures of Incandescent Lamp Filaments," BENJAMIN E. SHACKLEFORD.

"Temperature Measurements of Incandescent Gas Mantles," H. E. IVES.

"Application of Pyrometry to Problems of Lamp Desire and Performance," I. H. VAN HORN.

"Use of Modified Rosenhain Furnace for Thermal Analysis," H. SCOTT and J. R. FREEMAN.

"High Temperature Thermometers," R. M. WILHELM.

"Temperature of a Burning Cigar," T. S. SLIGH and C. S. KRAYBILL.

"Teaching Pyrometry in Our Technical Schools," GEORGE V. WENDELL.

"Teaching Pyrometry," C. E. MENDENHALL.

"Teaching Pyrometry," O. L. KOWALKE.

"Present Status of Radiation Constants," W. W. COBLENTZ.

"Pyrometer Protection Tubes," OTIS HUTCHINS.

Friday, Sept. 26

Continuation of adjourned Technical Sessions:

MORNING

Optional Trips.

1. North Chicago and Milwaukee.
2. East Chicago metallurgical plants and oil refineries at Whiting, Indiana.
3. Local Chicago plants.
4. Coal trip to Franklin and Macoupin counties.

Technical Association of the Pulp and Paper Industry

The following tentative program of meetings, excursions and entertainments of the Technical Association of the Pulp & Paper Industry, Chicago, has been prepared. More extensive details appear in the final program.

Sept. 24, 25, 26 and 27—All meetings are to be held in conjunction with the Fifth National Exposition of Chemical Industries in the officers' Board

Room of the First Regiment Armory, Sixteenth St. and Michigan Boulevard, and at the Coliseum, Wabash Ave. and Fifteenth St., Chicago. Admission by T. A. P. I. badge. Members are requested to register at T. A. P. I. booth, No. 237, and at the entrance to the Armory, immediately on arrival any time during the week.

Wednesday, Sept. 24

10 A.M.

Opening meeting in First Regiment Armory.

Address of welcome.

Opening remarks by the president.

Report of the executive committee.

Report of the secretary-treasurer, followed by reports of standing committees:

Abstracts of Literature, ROSS CAMPELL, chairman.

Bibliography, HENRY E. SURFACE, chairman.

Heat, Light and Power, EDWARD P. GLEASON, chairman.

Paper Testing, FREDERICK C. CLARK, chairman.

Soda Pulp, MARTIN L. GRIFFIN, chairman.

Standard Methods of Testing Materials Used in the Manufacture of Paper, WILLIAM H. GESELL, chairman.

Sulphate Pulp, OLAI BACHE-WIIG, chairman.

Sulphite Pulp, HERBERT G. SPEAR, chairman.

Vocational Education, GEORGE E. WILLIAMSON, chairman.

Among the special papers and reports to be presented and discussed is one entitled "The Principles and Practice Involved in Washing Unbleached Soda Pulp." This will form the report of the committee on Soda Pulp, MARTIN L. GRIFFIN, chairman.

The committee on Sulphate Pulp, O. BACHE-WIIG, chairman, will make a report on tests which have been made to determine the loss of soda in the evaporation of black liquor in sulphate mills. The report is not expected to be a lengthy one, but it will be characterized by great accuracy, the tests having been made by the same chemists in a number of different pulp mills. Methods of overcoming avoidable waste will be described in the report.

The committee on Paper Testing, FREDERICK C. CLARK, chairman, promises a revised report on methods of testing paper which should prove of great interest and value.

3:30 P.M.

Adjourned session in First Regiment Armory.

The committee on Sulphite Pulp will report on new methods of handling waste liquor from digesters and of cooling the SO₂ gas from burners.

An account of research work on the important problem of waste sulphite liquor utilization will be presented by Prof. RALPH H. MCKEE and GEORGE BARSKY, of Columbia University, in a paper entitled "Fuel From Waste Sulphite Liquor."

6:30 P.M.

Dinner at the Union League Club.

Thursday, Sept. 25

9:30 A.M.

Business meeting at Registration Booth in Coliseum.

1 P.M.

Adjournment for visit to paper mill plant of Sears, Roebuck & Co.; luncheon as guests of the firm.

2 P.M.

Inspection tour of the Sears, Roebuck & Co., plant.

4 P.M.

Committee meetings and special papers.

7 P.M.

Illustrated address by Dr. R. J. BLAIR, pathologist, Forest Products Laboratories of Canada, McGill University, Montreal, on "Prevention of Decay in the Timber of the Roofs of Pulp and Paper Mills," followed by smoker and entertainment.

Friday, Sept. 26

The day will be spent in a visit of inspection to the Forest Products Laboratory of the Forest Service, U. S. Department of Agriculture, Madison, Wis. Train arrangements provide for members taking a late train from Chicago on Thursday evening and arriving in Madison early Friday morning, or leaving late in the afternoon so as to reach Madison shortly after 9 o'clock in the evening. Hotel accommodations at Park Hotel. The departure from Madison will be made on Friday at 5:40 P. M., arriving in Chicago at 10:30 P.M. The first class fare from Chicago to Madison is \$4.21, and sleeper berth \$1.60. Notice of intention to take the trip should be sent promptly to Chairman Savery.

Saturday, Sept. 27

9:30 A.M.

Adjourned business sessions at the National Exposition of Chemical Industries.

American Ceramic Society

Program for "Ceramic Day" at the Fifth National Exposition of Chemical Industries, the Coliseum, Chicago, Sept. 24, 1919.

10 A.M.

"The American Ceramic Society, Past, Present and Future," Prof. CHARLES F. BINNS.

"Buy on Analysis," Dr. ALEXANDER SILVERMAN.

"Superior Refractories," ROSS C. PURDY.

"The Making of Pottery," FREDERICK H. RHEAD.

2:30 P.M.

"General Types of Optical Glass," ROBERT J. MONTGOMERY.

"Brick and Tile," DOUGLAS F. STEVENS.

"The Application of Scientific Methods to Ceramic Research," A. V. BLEININGER.

"The Manufacture of Optical Glass," Dr. J. C. HOSTETTER.

"Enameling Technology," R. R. DANIELSON.

Other addresses will be delivered at both morning and afternoon sessions.

8 P.M.

Motion pictures, including:

1. "Making Cut Glass."
2. "Glass Bulb and Tubing Manufacture for Mazda Lamps."
3. "Making Window Glass."

BANQUET

It is urged that all members and their friends attend the dinner at 6 P.M., New Southern Hotel, 1250

South Michigan Ave., very near the Coliseum. Tickets at \$2 each can be secured at the Society's booth, No. 229, during the day, Sept. 24.

HEADQUARTERS

The headquarters of the American Ceramic Society throughout the Exposition week will be at Booth 229, at which representatives of the Society will be in constant attendance. It is urged that all members make their headquarters at the booth and everyone who is any way interested in the silicate industries will be most welcome. Any information which can be gotten for the assistance of any visitor will be obtained. At the booth there will be literature regarding the ceramic industry and the American Ceramic Society.

American Steel Treaters' Society

Tuesday, Sept. 23

9 A.M.

Registration Seventh Regiment Armory.

10 A.M.

Address of welcome: Hon. HARRY H. MERRICK, president Chicago Association of Commerce.

Address of welcome: Acting President T. E. BARKER.

Report of Acting Board of Directors by Acting Secretary A. G. HENRY.

Report of Finance Committee: Acting Chairman A. F. BOISSONEAU.

Paper: "Relation of Heat Treatment, Design and Selection of Steels for Metal Cutting Tools to Factory Production;" C. P. BERG, president C. P. Berg & Co., consulting engineers.

Visit to Exhibits.

2 to 4:30 P.M.

Presiding officer, HORACE H. CLARK, chairman Chicago Chapter.

2 P.M.

Report of tellers of election. Address of president-elect.

Papers: "Heat Treatment of Steels for Cutting Purposes."

8-10 P.M.

Presiding officer, G. WALTER ESAU, chairman Milwaukee Chapter. Papers: "Case Hardening in General."

Wednesday, Sept. 24

10-12 A.M.

Presiding officer, DAVID BELL, chairman Buffalo Chapter. Papers: "Heat Treatment of Miscellaneous Products."

2-4 P.M.

Presiding officer, B. F. WESTON, chairman Pittsburgh Chapter. Papers: "Heat Treatment of Steel for Intermittent Cutting Purposes."

8-10 P.M.

Presiding officer, GEORGE W. PRESSELL, chairman Philadelphia Chapter. Papers: "Results of Investigation Pertaining to Heat Treatment."

Thursday, Sept. 25

10-12 A.M.

Presiding officer, W. S. BIDDLE, chairman Cleveland Chapter. Papers: "Heat-Treating Equipment."

2-4:30 P.M.

Presiding officer, FRANK P. FAHY, chairman New York Chapter. Papers: "Solution of Modern Demands on Heat Treating."

6:30 P.M. Sharp

Informal banquet and entertainment, Cameo Room. Morrison Hotel. Tickets \$3.

Friday, Sept. 26

10 A.M.

Exhibit at Seventh Regiment Armory. Plant visitation.

7-10 P.M.

Band concert. Third Regiment Military Band.

Saturday, Sept. 27

"Chicago Day."

Exhibition open 10 A.M.-10 P.M.

1:30 P.M. and 7 P.M.

Band Concert. Third Regiment Military Band.

The Papers

An extensive list of papers, covering the very latest developments in every field of the heat-treating art, has been prepared. The papers given below form but a small part of the completed program:

"Modern Pyrometry," A. W. ANDERSON, C. S. Gordon Co.

"Metallography of Steel," CYRIL J. ATKINSON, Laboratories, Milwaukee, Wis.

"Annealing Large Sections of Cast Nickel Steel," G. A. BREWSTER, American Steel Foundries, Chicago, Ill.

"Salts for Quenching," SHIPLEY N. BRAYSHAW, London, England.

"Relation of Heat Treatment, Design and Selection of Steels for Metal Cutting Tools to Factory Production," C. P. BERG, C. P. Berg & Co., Chicago, Ill.

"Results of Investigations Pertaining to Heat Treating," RAY T. BAYLESS, James H. Herron Co., Cleveland, Ohio.

"Pyrometry," R. P. BROWN, president Brown Instrument Co., Philadelphia, Pa.

"Cast Steel," ALVIN N. CONARROE, chemist and metallurgist, National Malleable Castings Co.

"Electric Heating of Steel," E. F. COLLINS, General Electric Co.

"Case Hardening in General," WILLIAM G. CONNER, George D. Whitcomb Manufacturing Co., Rochelle, Ill.

"Heat Treatment of Balls for Bearings," ARTHUR L. COLLINS, Atlas Ball Co., Philadelphia.

"Effects of Forging Temperatures on Heat Treatment of Steels," D. R. CORNELL, Standard Forgings Co., Indiana Harbor, Ind.

"Heat Treatment of Cast Steel," WILLIAM GEORGE DAUNCEY, Associate Editor, *Iron and Steel*, Montreal, Canada.

"Heat Treatment of Cast Steel in Tractor Construction," FRED GROTTIS, Holt Manufacturing Co., Peoria, Ill.

Chicago Exhibitors

The following societies and publications will have booths, in which they will be glad to receive their friends:

AMERICAN CERAMIC SOCIETY.
AMERICAN CHEMICAL SOCIETY.
AMERICAN DYES INSTITUTE.
AMERICAN ELECTROCHEMICAL SOCIETY.
CANADIAN CHEMICAL JOURNAL.
CANADIAN MINING JOURNAL.
CANADIAN TEXTILE JOURNAL.
CHEMICAL CATALOGUE CO., INC.
CHEMICAL & METALLURGICAL ENGINEERING.
CHEMICAL ENGINEER.
CHICAGO SECTION, AMERICAN CHEMICAL SOCIETY.
COLOR TRADE JOURNAL.
INDUSTRIAL & EDUCATIONAL PRESS.
IRON & STEEL OF CANADA.
JOURNAL OF COMMERCE.
JOURNAL OF INDUSTRIAL AND ENGINEERING CHEMISTRY.
MCGRAW-HILL CO.
MANUFACTURERS' RECORD.
OIL, PAINT & DRUG REPORTER.
PAPER.
PULP & PAPER MAGAZINE OF CANADA.
TECHNICAL ASSOCIATION OF THE PULP & PAPER INDUSTRY.
TEXTILE COLORIST.

The names of the representatives and brief itemization of products of the exhibitors are given as received up to the closing date of this issue. Over 330 firms are taking advantage of the excellent opportunity offered in the Chicago Exposition to extend their acquaintance in the Central States.

PAUL O. ABBE—Crushing, cutting, pulverizing, disintegrating, mixing and sifting machinery. Special features—motor-driven, self-contained unit jar and pebble mills, Gruendler hammer mills, Mead mills, etc. In charge of exhibit: Paul O. Abbe, Henry Sellman and John Buckley.

ABBE ENGINEERING CO.—Pebble mills, disintegrators, Max mills, bolting cloth, featuring motor-driven laboratory mills. In charge of exhibit: H. F. Kleinfeldt and W. S. Ransom.

THE ABBOTT LABORATORIES—Synthetic pharmaceuticals, such as barbital, chlorazene, chlorosane, dichloramine-T, histidine, calcium, copper, mercury, sodium and zinc phenolsulphonates, etc. The features of the exhibit will be a working model of the manufacture of chlorazene from coal tar, and a physiologic testing demonstration of anesthetics and hypnotics. In charge of exhibit: W. F. Straub, E. H. Vollweiler, Carl Nielsen and Norman Hansen.

WILLIAM AINSWORTH & SONS.—Three analytical balances. In charge of exhibit: A. W. Ainsworth.

ALBANY FELT CO.—A complete line of all wool-woven filter cloths for the various methods of filtration. These cloths work most successfully in aniline dye plants and also in plants manufacturing the heavier chemicals. There will also be samples of paper mill felts used by manufacturers of newsprint, bonds, writings, tissues, boards and pulps. In charge of exhibit: Walter S. Rooney.

THE ALBERENE STONE CO.—Various laboratory equipment including a standard hood, consisting of a complete superstructure of Alberene stone and wireglass with sliding sash, work-tables, reagent shelves and a chemical sink with drain-board and pegboard for washing and drying glassware. A special photograph tank for X-ray purposes will be found of interest to physicians and others interested in X-ray work. In charge of exhibit: Warren K. Fields, F. A. Buss.

ALLEN ELECTROLYTIC CORP

AMERICAN BALLAST CO. (formerly the AMERICAN LIMESTONE CO.)—Various kinds of limestone in various conditions of preparation from a sample of rock down to ground material, which will be 200-mesh in fineness. In charge of exhibit: Scott A. Fones.

AMERICAN CHEMICAL & MANUFACTURING CO.—"Hippo" waterproofing products, including acid, water and shower proof textiles; waterproof concrete, concrete floor hardener; acid-proof, oil-proof, brine-proof coatings for steel; lacquers for food tins, etc.; insulating varnishes for transformer coils; wall primer to prevent leaching of calcium salts. In charge of exhibit: Charles D. Stillman, W. M. Van Ostrom and R. C. Dederick.

AMERICAN CYANAMID Co.—The principal features will be a series of models accompanied by brief descriptive matter showing the process of fixing nitrogen from the air in the form of cyanamide together with samples of all cyanamide products, with brief descriptions of their principal uses. In charge of exhibit: E. J. Pranke and J. P. Hubbell.

AMERICAN HARD RUBBER Co.—An electrically driven hard rubber centrifugal pump, pumping through a hard rubber pipe into hard rubber tanks. The only material which comes in contact with the liquid is hard rubber. Small reciprocating pumps and other articles will illustrate the various uses to which hard rubber can be put. In charge of exhibit: A. M. Ackerman and E. D. Madden.

AMERICAN KRON SCALE Co.—One of the standard portable scales of the type adopted by the American Railway Express Co. will be exhibited to demonstrate claims as to durability and strength. In charge of exhibit: Carl F. Larson and John M. Bjornson.

AMERICAN LA FRANCE FIRE ENGINE Co.

AMERICAN METAL PRODUCTS Co.—"Ampeco" metal, both castings and sheet, including valves, calorimeter bombs, runners, liners, etc. designed to resist the corrosive action of all commercial acids. In charge of exhibit: H. C. Brelic, Miss E. T. Smith, R. W. Alger and C. J. Zaiser.

AMERICAN METER Co.—A No. 302 calorimeter set, new type of cubic foot standard as described in technologic paper No. 114 of Bureau of Standards, a $\frac{1}{2}$ -cu.-ft. bottle, set of gages, specific gravity apparatus, service cleaner, and various types of test meters. In charge of exhibit: H. D. Harper and J. G. Barrett.

AMERICAN ROLLING MILL Co.

AMERICAN TRANSMARINE Co.

AMERICAN WATER SOFTENER Co.

ANACONDA COPPER MINING Co.—(See Raritan Copper Works).

H. REEVE ANGEL & Co.—Whatman filter papers, including two new products, viz: Strips for arsenic determinations and absorption blocks. Filter papers of American manufacture, including the Alpha No. 190, Lion, Griffin Gray and Climax brands. "Labruco" pure gum rubber tubing, filter mass, glass wool, etc. In charge of exhibit: Byron S. Proper.

ANILINE DYES & CHEMICALS, INC.

ARKELL SAFETY BAG Co.—Linings for shipping packages such as barrels, boxes, drums and bags. The linings will be shown inserted into the different packages ready for use. In charge of exhibit: P. J. Morales and John B. Judson, Jr.

ARMSTRONG CORK Co.—Insulating material for hot and cold surfaces; nonpareil corkboard insulation for refrigerated and constant temperature rooms, nonpareil cork covering for cold pipes and tanks, nonpareil insulating brick for furnaces and other high temperature equipment. The feature will be an electrically heated furnace so arranged as to give a tangible demonstration of the difference in the heat-conducting qualities of nonpareil brick and ordinary brick. In charge of exhibit: S. L. Barnes.

ARNOLD, HOFFMAN & Co., INC.—A joint exhibit with the MATHIESON ALKALI WORKS and the NITROGEN PRODUCTS Co. (q.v.). Finishing and sizing materials for textile and other trades and a line of pigment colors. In charge of exhibit: Adriaan Nagelvoort, Otto A. Fritz and H. D. Winship.

W. O. ARZINGER MACHINERY Co.—A complete working model of the simplex flotation process on straight and selective flotation. In charge of exhibit: W. O. Arzinger.

ATLAS ELECTRIC DEVICES Co.

ATLAS POWDER Co.—Special bottles of chemical products, high explosives, dynamite, blasting supplies and blasting powder. In charge of exhibit: E. E. Reese, E. L. B. Baptiste and H. V. Clark.

THE AUSTIN Co.—Photographs and descriptive matter of some of the chemical plants designed, constructed and equipped by this company. Working models of Austin standard buildings, together with actual sections of the materials entering into their construction. In charge of exhibit: C. F. Chard.

BACHMEIER Co., INC.—An exhibit of aniline dyes. In charge of exhibit: J. H. Bachmeier, G. M. Lord and E. J. Struck.

BAILEY METER Co.—Various types of Bailey fluid meters for measuring steam, water, gases and chemicals; V-notch Weir meter, 50,000 lb. per hour capacity, in operation; two fluid meters in operation, one with orifice in 4-in. water line, the other with orifice in 6-in. air line. In charge of exhibit: E. G. Bailey and W. E. East.

J. T. BAKER CHEMICAL Co.—A line of chemical reagents specifically known as "Baker's analyzed chemicals." In charge of exhibit: William P. Fitzgerald.

BAUSCH & LOMB OPTICAL Co.

THE BARRETT Co.—Joint exhibit with National Aniline & Chemical Corporation, General Chemical Co., Semet-Solvay Co., and the Solvay Process Co. The Barrett Co. will contribute a chart showing (by means of samples) the interrelation of about 200 coal-tar products. A newly developed coal-tar resin, paracoumarone (trade name Cumar); Naphthalene; benzols, toluols; phenols, cresols, cresylic acids, etc., will also be shown. In charge of exhibit: H. S. Sidebottom, F. E. Dodge, R. O. Phillips, C. P. Brown, W. W. King, R. P. Dunning, W. B. Rogers and W. E. Lupe.

BEACH-RUSS Co.—Vacuum pumps, pressure blowers, oil pumps, acid pumps, gas boosters, pebble mills, rotary cutters and laboratory mills, featuring high-vacuum pumps guaranteed to exhaust to within $\frac{1}{10}$ in. of barometer. In charge of exhibit: C. A. Beach, H. C. Russ and W. S. Ransom.

CHRISTIAN BECKER, INC.—Chainomatic balances, featuring specific gravity chainomatic balance, which has only recently been placed on the market. With this balance determinations are speedily made and readings are taken directly from the graduated scale, the Vernier reading to the fourth decimal place. Model No. 100 has a range of 0.400 to 2.000. In charge of exhibit: A. T. Millroy, D. Taylor, S. W. Hess and William L. Ferdon.

BECKLEY PERFORATING Co.—Perforated material of various descriptions and electrically welded tanks and specialties. In charge of exhibit: Otis Wright and Allen Price.

BEIGILLIE ELECTRIC Co.—(See Cleveland Instrument Co.).

BENJAMIN ELECTRIC MFG. Co.

BLACKMER ROTARY PUMP Co.—A special unit for use in chemical plants consisting of a rotary pump mounted on cast iron sub-base and direct-connected to an electric motor, the complete unit being mounted on swivel casters, so that it can be moved from one part of the factory to another, in this way taking the place of several units. The pumps are provided with an automatic feature for taking up wear and removable linings, which can be changed in a few minutes. In charge of exhibit: J. H. Oldham and Arthur J. Schmitt.

BLAIR, CAMPBELL & McLEAN, INC.—A small size patent centrifugal gas and vapor scrubber so constructed that the inside mechanism can be readily inspected. In charge of exhibit: B. Dunglinson and A. C. Wood.

BOUND BROOK CHEMICAL Co.

BOYER OIL Co.—Samples of the different oils and oil cake meals manufactured by the company. In charge of exhibit: Mr. Carper.

THE BRISTOL Co.—Recording and indicating instruments for pressure, temperature and electricity. In charge of exhibit: H. G. Hall.

THE BROWN INSTRUMENT Co.—A complete line of high and low temperature measuring instruments, including indicating and recording thermometers and pyrometers for use in the chemical industry and for the control of high-temperature processes. Brown resistance thermometer for low temperature work. Indicating and recording pressure gages for air, vacuum, oil, water, draft, etc. Indicating and recording tachometers. In charge of exhibit: R. P. Brown, G. W. Keller, J. W. Lazear, F. C. Mahoney, R. E. Soules, S. W. Thal and Richard Guest.

BROWN PORTABLE CONVEYING MACHINERY Co.—Two of the latest designs: a portable belt conveyor for handling loose materials and a portable tiering machine, the "Handlift." This last machine has three speeds and the brake is quick-acting and foolproof. The belt conveyor will handle any form of loose material and has an ingenious scoop or shovel end which allows the material to be scraped on to the belt. In charge of exhibit: Harwood Frost and Elmer D. Bushnell.

BUFFALO FOUNDRY & MACHINE Co.—Chemical apparatus: Vacuum driers of various types, including a vacuum drum drier in operation; evaporators, featuring a special type rapid circulation evaporator; kettles, autoclaves, caustic pots, nitrators, etc. In charge of exhibit: E. G. Rippel and others.

BUTTERWORTH-JUDSON CORP.—Mill dyeings of chrome colors on men's wear and dress goods; also a complete set of raw stock dyeings. In charge of exhibit: W. H. Clark and Edward A. MacKinnon.

CANADA CARBIDE Co.—Samples of carbide, showing the various sizes in which it is manufactured for domestic and foreign trade. In charge of exhibit: H. E. Mussett.

CANADIAN ELECTRODE Co.—Special features will be a 17-in. round amorphous carbon electrode and a 16 by 16 in. square amorphous carbon electrode, each approximately 5½ ft. long. In charge of exhibit: H. E. Mussett.

CANADIAN ELECTRO PRODUCTS CO., LTD.—Synthetic organic products derived from acetylene, including glacial acetic acid, paraldehyde, aldamine, acetaldehyde, acetic anhydride. In charge of exhibit: V. C. Bartram.

CANADIAN NATIONAL RAILWAYS.

THE CARBORUNDUM CO.—Carborundum refractories, including carbofrax and refrax brick, tile, muffles, tubes; carborundum refractory cement; carbofrax saggars, fire-sand; silicon metal; carborundum and aloxite wheels, paper and cloth. In charge of exhibit: Otis Hutchins, M. L. Hartmann, S. C. Linbarger and C. E. Hawke.

CARNOTITE REDUCTION CO.

CARRIER ENGINEERING CORP.—A complete operating installation of Carrier humidifying equipment, including the humidifier, fan and motor and automatic control instruments regulating the air delivery. The fan outlet will be provided with a diffuser so that the effects of the humidifier can be observed by noting the condition of the effluent air. In charge of exhibit: E. P. Heckel, H. B. Matzen and J. E. Bolling.

CELITE PRODUCTS CO.—Demonstrations and illustrations showing the use of Sil-O-Cel for heat insulation in various industries and also various applications of Filter-Cel, a material used for filtering various liquids. Typical uses of Celite, a light weight mineral filter, will also be illustrated. In charge of exhibit: P. A. Boeck, Thomas G. Lee, A. W. Knight and others.

CELLULOID ZAPON CO.—Unlimited color range of Zapon air drying enamels will be shown on merchandise as small as beads and as large as furniture. Silverware and highly polished metal will portray the value of Zapon air drying lacquer. Various types of products requiring a dipped or sprayed finish will also be shown. In charge of exhibit: Frank P. Davis, and representative from the New York office.

CENTRAL SCIENTIFIC CO.—DeKhotinsky constant temperature drying ovens, incubators, water baths and thermostats. The Cenco-Nelson high vacuum pump, Cenco hydrogen ion determination apparatus, Cenco electric heater for gasoline distillation, duNouy surface tension apparatus, gas analysis apparatus of various types. In charge of exhibit: S. L. Redman, A. B. Carter, S. R. Evans, E. C. Leamon and others.

CHALLENGE CO.—(See Tower and Wooden Tank Industrial Council).

CHEMICAL CONSTRUCTION CO.—Detailed plans of acid plants. Materials used in acidproof masonry construction and a model acid tower built of acidproof brick and cement showing interior construction. In charge of exhibit: T. C. Oliver and R. L. Rutzler.

CHEMICAL EQUIPMENT CO.

CHEMICAL FOUNDATION, INC.

CHICAGO PNEUMATIC TOOL CO.—Simple valve air compressor, electrically operated; Boyer pneumatic hammers; pneumatic, riveting, chipping, calking and scaling hammers; Little Giant pneumatic and electric drills and grinders; "Hummer" and valveless type rock drills, etc. In charge of exhibit: W. P. Pressinger, H. L. Dean, T. J. Hudson, C. B. Coates and others.

ANTOINE CHRIS CO.—A comprehensive line of essential oils and synthetic chemical products; exhibit of successive steps in the manufacture of selected products from the raw materials; Capes viscose as applied to various types of packages. In charge of exhibit: G. F. Richmond.

THE CLEVELAND-CLIFFS IRON CO.—Materials obtained from wood by the wood carbonization process, including methyl alcohol, acetone and acetic acid. In charge of exhibit: Charles B. Hall.

THE CLEVELAND INSTRUMENT CO., successor to the BEIGH-LEE ELECTRIC COMPANY, INC.—Recording and indicating pyrometer equipment of both resistance and thermo-electric type, the latter using a patented compensating feature which takes care of variations in the cold junction of the thermocouples thus obviating the necessity of expensive lead wires and burying the cold junction. In charge of exhibit: W. H. Chappeal.

CLINCHFIELD PRODUCTS CORP.

CONTACT PROCESS CO.—Sulphuric acid, muriatic acid, mixed (nitrating) acid, nitric acid, salt cake, etc. In charge of exhibit: E. K. Henderson, Dr. von Rucker and Truman Smith.

COORS CHEMICAL PORCELAIN CO.

CORNING GLASS WORKS—Glass laboratory apparatus made of pyrex glass. In charge of exhibit: G. Willis Drake, Irving B. Cary, F. F. Pfeiffer and F. Kraissl.

CRANE CO.—A complete line of valves and fittings for handling of steam, air, gas and water in chemical plants;

electrical temperature control valve for maintaining constant temperature; working exhibit of Cranetile traps for handling condensation under low and high pressure. In charge of exhibit: Edmund Burke, W. L. Goddard, F. E. McCreary, W. A. Dallach, R. M. Miller and W. F. Lambin.

CRANE PACKING CO.—"John Crane" flexible metallic packing in coil and ring form—a packing suitable for steam, air, ammonia, sulphuric acid, and which can be used in the form of gaskets on condensers and evaporators. In charge of exhibit: F. E. Payne, H. W. Lamb, K. M. Bickel.

A. DAIGER & CO.—Standard chemical equipment with special chemicals and equipment developed to meet the recent necessities. In charge of exhibit: Charles Rascher and R. I. Wishnick.

THE J. H. DAY CO.—Special mixing machines for powders, paste and heavy masses; also grinding machinery. In charge of exhibit: C. F. Cone and F. M. Dudley.

THE DELAVAL SEPARATOR CO.—DeLaval oil purifier, varnish clarifier, yeast separator, blood albumen separator, centrifugal filter and gasoline purifier. With each machine there will be an exhibit of the materials handled by the machine showing the different stages from raw material to finished product. In charge of exhibit: H. C. Beckman, H. M. Beach, C. F. Meissner, A. Alexander and others.

THE DENVER ENGINEERING WORKS CO.—Ruth counter current flotation machine and the Richards pulsator jig, with working models in operation. In charge of exhibit: Alfred Tellman and Joseph P. Ruth.

THE DENVER FIRE CLAY CO.—A full line of fire clay specialties; new large-size melting crucible; low-pressure fuel oil furnace, oil crushers, samplers, sieves, and a complete set of the Lind interchangeable electrocope. In charge of exhibit: L. W. Hoshour and George W. Lindsay.

DETROIT ELECTRIC FURNACE CO.—A 500-lb. Detroit electric furnace for non-ferrous metals. In charge of exhibit: E. L. Crosby, A. E. Rhoads, H. M. St. John, M. G. Carhart and George B. Cross.

THE DETROIT RANGE BOILER & STEEL BARREL CO.—A complete line of Detroit drums and Perfect metal bilge barrels, the latter being in two styles, a tight package for shipment of liquids of a volatile nature and a package with a removable head which is designed for shipment of solids or semi-solids. In charge of exhibit: E. W. Sanborn and A. L. Lindeblad.

J. P. DEVINE CO.—Chemical apparatus such as chemical kettles, autoclaves, carbonators, small vacuum drying chambers (which will serve to illustrate the features of the large vacuum driers), motor-driven vacuum pumps. THE KEK MANUFACTURING CO., a subsidiary, will exhibit the Kek grinding and pulverizing mill in two sizes. In charge of exhibit: J. P. Devine, C. P. Devine and George Galloway.

DIAMOND STATE FIBRE CO.—A general line of fiber sheets, rods and tubes, together with special parts such as gears, gaskets, combs, etc. Protective paper: greaseproof, vegetable parchment, parchmentoid, glassine and filter paper. In charge of exhibit: Theodore Herkert and B. M. Lewis.

DINGS MAGNETIC SEPARATOR CO.—Several types of magnetic separators; Type "M" No. 1 unit, magnetic pulley type separator, standard Wetherill high intensity unit. The two former are used for extracting strongly magnetic material from chemical products, and the Wetherill machine is applied very successfully to the concentration of minerals, chemicals, etc. In charge of exhibit: R. A. Mane-gold, E. S. Hirschberg and G. H. Fobian.

DOMINION WATER POWER BRANCH.

THE DORR CO.—The Dorr tray thickener, the Dorroco pump and Dorr bowl classifier will be shown in closed circuit operation on a semi-commercial scale demonstrating their application in a typical problem of separating and dewatering two products of different physical character. Samples of materials handled with or produced by Dorr equipment will also be shown. In charge of exhibit: H. N. Spicer, C. Lee Peck, F. F. Peters, P. M. McHugh, E. R. Ramsay and G. W. Repetti.

THE DOW CHEMICAL CO.—Samples of the 86 products manufactured by the company will be shown, duplicate samples being provided with loose stoppers for convenience in closer examination. Two new products will be shown, phenyl-ethyl-alcohol and di-phenyl-oxide. The oxychloride cement floor will be demonstrated in one corner of the booth and by means of an abrasive machine the wearing qualities of this type of flooring will be compared with those of the ordinary concrete floor. In charge of exhibit: D. A. Newland and R. K. Snow.

F. W. DRACKETT & SONS CO.

DRAPER MFG. CO.

DRYING SYSTEMS, INC.

DUNCK TANK WORKS.—(See Tower and Wooden Tank Industrial Council).

DURIRON CASTINGS Co.—Acidproof equipment, including pumps, fans, ejectors and pulsometers, improved type condensers, concentrators for sulphuric and other acids, mixing kettles, denitrator towers and a full line of standard Duriron pipe and fittings. In charge of exhibit: Pierce D. Schenck, Joseph Dart, Jr., R. F. Schmidt, G. A. Cocup, J. W. Swann, E. A. Suverkrop and R. H. B. Elkins.

EAGLE TANK CO.—(See Tower and Wooden Tank Industrial Council).

EASTMAN KODAK Co.—Research organic chemicals for university laboratories. In charge of exhibit: I. N. Hultman, Miss Anne W. Davis and Miss Ethel Schram.

ECONOMIC MACHINERY CO.

ECONOMY ENGINEERING CO.

EDGAR BROS. CO.

THE EGYPTIAN LACQUER MFG. CO.—A comprehensive and varied line of finished articles showing application of lacquers, thinners, enamels and similar products. In charge of exhibit: G. W. Griffiths, Nathan P. Hunter, Simeon Smith and G. J. Henry.

ELMER & AMEND—A general line of laboratory apparatus with several new laboratory specialties as well as improved types of standard apparatus. In charge of exhibit: C. G. Amend, W. R. Elmer, T. M. Saulters, L. E. Flugler and F. C. Eibell.

THE ELECTRIC FURNACE Co.—Baily electric furnace of standard type melting copper together with specimens of the wide range of products that are being melted in American foundries in this furnace. In charge of exhibit: T. F. Baily, R. F. Benzinger and F. J. Peterson.

ELECTRO BLEACHING GAS Co.—Chlorine control apparatus, containers for transporting chlorine gas, and samples of textile fabrics bleached and finished by the use of liquid chlorine. THE NIAGARA ALKALI Co. will have an exhibit in the same booth consisting of small samples of various alkali products, including caustic soda and potash.

ELECTROLYTIC ENGINEERING CO.

ELECTRON CHEMICAL Co.—A model size of the 12/1500 amp. Allen-Moore cell, together with the latest addition to the Allen-Moore cell family; namely, the 50-amp. size. In charge of exhibit: Mr. Kent, R. Fox and H. D. Marsh.

G. H. ELMORE—Acidproof centrifugal pumps. These pumps are made of two distinct types for non-corrosive metallic alloys; the first recommended for use with acids such as acetic, formic, hydrofluoric, sulphuric, etc., and the second for nitric, hydrochloric, chromic and mixed acids, ammonium hydroxide, etc. In charge of exhibit: G. H. Elmore and A. C. Wood.

THE ELYRIA ENAMELED PRODUCTS Co.—Three new pieces of apparatus which have been developed recently: A 48-in. complete still, 250 gal. capacity; an 18-in. still, 10 gal. capacity, and a 100-gal. evaporating dish which is 60 in. in diameter and 24 in. deep. In charge of exhibit: J. E. Simpson, D. M. Webster, Fred B. Morris, W. E. Gray, E. P. Poste, R. F. Goerke and Max Donaver.

CHARLES ENGELHARD—Engelhard Le Chatelier pyrometers, platinum electric resistance thermometers, electric resistance type furnaces, transparent quartz glass, impervie refractories and porcelains. In charge of exhibit: E. S. Newcomb.

EVERLASTING VALVE Co.—Everlasting valve and Wilson cup valve. The effect of dilute sulphuric acid on various metals will be demonstrated in order to make a comparison with Aterite, a metal which is being used to make valves for certain acid work. In charge of exhibit: E. N. Corning and Ernest G. Jarvis.

FANSTEEL PRODUCTS CO., INC.

W. L. FLEISHER & CO., INC.—Model of air conditioning apparatus similar in design to that recently installed in several large plants. Model of driers for mineral, vegetable and animal products, together with samples of products dried in these machines. Models of typical power plant installations, direct and blast heating systems, ventilating layouts, and general layouts for industrial plants. In charge of exhibit: W. L. Fleisher, A. W. Dissauer and R. E. Keyes.

FOAMITE FIREFOAM Co.—A model of an oil refinery showing the efficiency of this method of extinguishing oil fires; a 40-gal. model "F" engine; 5-gal. steel extinguishers; 3-gal. approved Foamite fire pails; 2½-gal. approved copper Foamite firefoam extinguishers and recharges. In charge of exhibit: G. B. James and A. E. Canaday.

FOOTE MINERAL Co.—Display of unusual ores, rare elements and ferro-alloys, together with manufactured articles

into which they enter. A complete line of zirconia products with electric furnace to demonstrate the super-refractory qualities of Zirkite and Zirkonalba. In charge of exhibit: W. M. Foote, H. C. Meyer and W. A. Koenig.

THE FORESTS PRODUCTS LABORATORY, U. S. Department of Agriculture—Testing, preparation and application of various glues, particularly those used in aircraft manufacture.

THE FOXBORO CO., INC.—A new liquid level recorder with a special water seal, making it possible to use this instrument on oils and other liquids lighter than water which would naturally attack a rubber diaphragm. A new Foxboro-Henth CO. recorder and an automatic temperature controller will be in operation. In charge of exhibit: A. F. Mundy, F. W. Carrol, Mr. Neely and Mr. Roessner.

FUEL PRODUCTS CO.

FULLER-LEITCH CO.

WILLIAM GAERTNER & Co.—Instruments of precision. Cathetometer, comparator, spectroscope, spectrometer, gas and fuel calorimeters. Universal laboratory supports, laboratory telescopes and microscopes. In charge of exhibit: William Gaertner and C. D. Miller.

WM. GARRIGUE & Co.

CHAS. F. GARRIGUES Co.—Various grades of potash from first sorts to persulphate, caustic potash sticks of the U. S. P. pure white and alcohol purified grades; caustic soda sticks; benzoate of soda and benzoic acid, U. S. P. white odorless and tasteless; stearates of zinc and aluminum, etc. In charge of exhibit: H. D. Wellman, Mr. Campbell and Mr. Anderson.

GARY CHEMICAL CO., INC.—Ortho- and para-nitrotoluol. Ortho- and para-toluidine. In charge of exhibit: V. U. Young and Roger N. Holcomb.

GENERAL AMERICAN TANK CAR CORPORATION—Photographs and drawings of tank cars. In charge of exhibit: Hugh Epstein, Ralph Epstein and Joseph Epstein.

GENERAL BAKELITE Co.—A full line of Bakelite applications, including Bakelite varnish, lacquer, enamel, cement, transparent and colored material, molded parts, sheets, rods and tubes. A small Bakelite molding press will be in operation to show the fabrication of the material from the raw state to the finished article. In charge of exhibit: Hyllton Swan, Herbert S. May, William S. Gordon, Jr., and L. M. Rossi.

GENERAL CERAMICS Co.—Small models (averaging about 10 in. in height) of practically all of the acidproof stoneware containers, machines, etc., manufactured by this company. These models are exact reproductions of standard apparatus so that visitors will have an opportunity to inspect a complete line of acidproof stoneware. In charge of exhibit: Percy C. Kingsbury.

GENERAL CHEMICAL Co.—Standard acids and chemicals, also Ryzon baking powder and Orchard Brand insecticides and fungicides. A number of products manufactured by customers of the company will be shown, such as tin plate, glues, dyes, explosives, fertilizers, artificial leather, celluloid, pharmaceuticals, etc. In charge of exhibits: N. Peterkin and George P. Adamson.

GENERAL ELECTRIC Co.—A model of the Cottrell precipitation outfit used by the Gellert Engineering Co. for recovering potash from blast-furnace gases will be shown in operation. A KT-312-6-15-hp., 1200-r.p.m., 440-v. motor with frame and coils completely coated with an acid-resisting insulation, which is particularly adapted for use in chemical and fertilizer plants. A RC-24, 2-hp., 1150-r.p.m., 230-v. totally enclosed DS-2 shunt wound motor equipped with new Arguto plug bearings. In charge of exhibit: Chester T. McLoughlin, Raymond Barclay and other representatives.

GENERAL FILTRATION CO., INC.—Acidproof Filtros filter plates in various sizes, shapes and grades; electrofiltros acidproof diaphragms for electrolytic work; acidproof cement. In charge of exhibit: F. E. Leiby and W. W. Robacher.

GENERAL FIRE EXTINGUISHER Co.—The Grinnell automatic sprinkler will be installed in a large wire-glass house in which a fire will be started once every hour to show the automatic action of the sprinkler system in extinguishing a fire. The working principle of the sprinkler head will be demonstrated by a large working model 3 ft. high. In charge of exhibit: Frank V. Sackett, Howard E. Branch, Theodore Fertig, John G. Thomas, A. E. Gauslin, H. D. MacDonald, H. H. Duley, H. O. Booth, S. Dorais and J. F. Gilmore.

GLAMORGAN PIPE & FOUNDRY Co.—Models of continuous gas-fired limekiln and causticizing tower. Improved rotary continuous suction filter in operation. Caustic flaker in operation. In charge of exhibit: W. D. Mount and C. H. Himnant.

GLENS FALLS MACHINE WORKS—Pulp and paper machinery, including Glens Falls rotary sulphur burner, Woods thickener machine for guncotton and chemical pulp, and the new split-cam for quick repair work on screens. In charge of exhibit: James H. Haines and others.

GORDON DRYER CORP.—"AA" size Gordon high-efficiency atmospheric drier. This size has grown very popular among colleges and research laboratories, as it is an ideal type of unit for small batch production. There will also be on exhibition a "D" drier, this unit containing 500 sq. ft. of effective drying surface. Both outfits will be complete so that drying tests can be made for any interested customer. In charge of exhibit: Nathan Owitz, R. R. James, H. D. Harvey and Richard B. Hewitt.

GOULDS MFG. CO.

GROCH CENTRIFUGAL FLOTATION, LTD.—A new model flotation machine in which the impeller acts as a centrifugal pumps, sucking air and oil through a hollow shaft. On striking the impeller blades the oil is broken up into small bubbles and thoroughly mixed with the solution, giving ideal flotation conditions. In charge of exhibit: Frank Groch, N. C. Groch and T. Garster.

GRUENDLER PATENT CRUSHER & PULVERIZER CO.

THE GUERNSEY EARTHENWARE CO.—Chemical laboratory porcelain: Crucibles, filter plates, casseroles, combustion capsules, evaporating dishes, beakers, concentric rings, filter rings, dye pots, funnels, desiccator plates, combustion tubes, porous cells, etc. In charge of exhibit: Allan L. Goulding.

HAMILTON & HANSELL, INC.—A 500-lb. Rennerfelt furnace of the type which has been widely used in steel making and in the melting of ferrous and non-ferrous alloys. In charge of exhibit: H. A. DeFries and Thomas Hagelthorn.

HANOVIA CHEMICAL & MANUFACTURING CO.—Laboratory apparatus of pure transparent quartz glass featuring very fine quartz fibers for instrument suspension and special vacuum discharge tubes for rare gases. Platinum wound electric laboratory furnaces. Direct reading electric resistance thermometers for central station industrial temperature control. Quartz mercury vapor lamps for research work with ultra-violet rays. In charge of exhibit: E. W. Fisher.

HARDINGE CONICAL MILL CO.—An exact model of the Hardinge conical ball mill will be in operation. Large users of the Hardinge mill will be featured by name and photographs of their installations will be shown. In charge of exhibit: Captain Harlowe Hardinge.

HAUSER-STANDER TANK CO.—See Tower and Wooden Tank Industrial Council).

HAYNES STELLITE CO.

FRANK HEMINGWAY, INC.

S. S. HEPPWORTH CO.—Centrifugals of all types in operation including a large electrically driven two-speed centrifugal capable of handling five tons of material per hour; water-driven centrifugal; Macintosh ball-bearing centrifugal and an under-driven machine, suitable for products in small quantities or where there are fumes requiring the top to be sealed. Hand-operated and power-driven unloaders. In charge of exhibit: Bruno C. Lechler, C. A. Olcott and E. F. Babbitt.

HERCULES ENGINEERING CORP.—A nitrator and an autoclave, having certain distinctive features which should be of interest to operators whose work requires equipment of this sort. Interesting information on Hercules evaporators, concentrators and equipment for the generation, compression and liquefaction of gases. In charge of exhibit: R. D. Kehoe, A. R. Calvo, W. H. Campbell, T. J. Brewster and Richard Neuhaus.

HERCULES POWER CO.—A complete line of organic chemicals including organic acids, valerates, pyroxylin solutions, waterproof cements, soluble cotton and solvents. The special features will be sodium alginate (Algin No. 3), which is being used as a sizing material for split leather, leather cloth and other fabrics. In charge of exhibit: G. C. O'Brien and W. L. Holter.

HEROLD CHINA & POTTERY CO.

J. D. HOLLINGSHEAD CO.

HOOD, B. MIFFLIN, BRICK CO.

HOOKE ELECTROCHEMICAL CO.

HOSKINS MANUFACTURING CO.—Laboratory electric furnaces, hot plates and thermo-electric pyrometers of the indicating and recording types, featuring a new multiple recording pyrometer, which will be in operation. In charge of exhibit: C. F. Busse, W. D. Little and C. S. Kinnison.

HUFF ELECTROSTATIC SEPARATOR CO.—A half-size electrostatic separator operating with samples of various minerals, showing separation of copper and tin from tungsten, ilmenite from sand, rutile from zircon, lead from barytes, etc.

Plumb pneumatic jig, laboratory size, which is a dry process and for that reason is particularly adapted to the concentration of ores where water is scarce. In charge of exhibit: H. B. Johnson, F. R. Johnson, C. D. Burrage, Jr., and William E. McKee.

THE HUNTER DRY KILN CO.—Models of automatically controlled humidity driers as well as samples of various materials dried by this system. In charge of exhibit: Harry Hunter, O. M. Ragsdale and Arthur B. Stonex.

HYCO FUEL PRODUCTS CORP.

IDEAL STENCIL MACHINE CO.—Stencil machines for cutting paper stencils for marking shipments, stencil filing cabinets, stencil ink and other shipping-room supplies and equipment. In charge of exhibit: G. E. Berglund and J. W. Marsh.

INDUSTRIAL ELECTRIC FURNACE CO.

INDUSTRIAL FILTRATION CORPORATION—Open tank type of filter, rotary hopper dewaterer and the continuous rotary filter. In charge of exhibit: G. D. Dickey and H. B. Faber.

INNIS, SPEIDEN & CO.

IRVING IRON WORKS CO.—A platform consisting of different sizes of Irving-Subway reticulate grating, with stairways showing Irving safety steps. In charge of exhibit: W. E. Irving, P. L. Price and F. N. Dodge.

JEWELL POLAR CO.—Steam operated still together with storage tank in operation. Steam, gas and electric laboratory stills. In charge of exhibit: A. C. Jewell, R. E. Henry, J. E. Bloesser and George Hild.

JOHNSON & CARLSON—(See Tower and Wooden Tank Industrial Council.)

KEK MFG. CO.—(See J. P. Devine Co.)

KENART SYNTHETIC PRODUCTS CO.—Numerous synthetic perfume and flavor bases, among them several not previously manufactured in this country; several pharmaceutical products; synthetic and vegetable food colors and dyes. In charge of exhibit: S. Wilmer Kendall and Hugh S. Stewart.

KEWAUNEE MFG. CO.—Laboratory fixtures: Chemical case (919); fume hood (933); chemistry desks (895 and 939); dark-room desk (1424); peg board (1434); exhibit case (1460); combustion table (909). In charge of exhibit: F. H. Wiese, R. A. Hanna, William E. Mix, O. T. Louis, F. M. Hassett and R. G. Siple.

MAURICE A. KNIGHT—A full carload of large standard and special pieces of chemical stoneware apparatus, as well as several complicated and small pieces. In charge of exhibit: Maurice A. Knight, Charles Dennison, Percy Sawyer and Samuel J. Baril.

THE KOPPERS CO.—One of the features will be a display of coke and by-products in the proportions produced in the coking of Illinois coal in Koppers ovens, based on official records of the U. S. Bureau of Standards. A new type of by-product coke oven exhibited for the first time. Model of the Koppers by-product coke oven. In charge of exhibit: E. L. Crowe and E. H. Bird.

LAMBERT & MANN CO.—Several sizes and styles of rotary dry vacuum pumps, some of which will be in operation. In charge of exhibit: Donald Rosie, Lawrence Eisenbies and R. F. Lambert.

LEAD LINED IRON PIPE CO.

LEEDS & NORTHRUP CO.—Different forms of apparatus—some of which will be shown in operation—for electrically determining the acidity or alkalinity of solutions. Equipments for electrolytic conductivity measurements, and an automatic recorder, which can be applied to recording changes in any process in which such changes are accompanied by changes in electrolytic resistance. Hand-operated and automatic recording potentiometers for temperature measurements of various ranges; a White combination potentiometer for precision thermocouple measurements; an optical pyrometer for accurate determinations of high temperatures, above the range of thermocouples; and other forms of apparatus of interest to chemists. In charge of exhibit: Paul E. Klopsteg, I. Melville Stein, G. W. Tall, Jr., H. Brewer and O. Brewer.

LINDSAY LIGHT CO.

THE LIQUID CARBONIC CO.—A working exhibit demonstrating the methods and apparatus used to adapt CO₂ to such pressures and temperatures as are required for its use in commercial processes. Complete outfits for large and small users, pressure regulators and tempering coils for CO₂, oxygen, acetylene and other gases. In charge of booth: J. H. Pratt, E. D. Hale, W. S. Hopkins and R. D. Crisp.

ARTHUR D. LITTLE, INC.—Pictures of the firm's building and laboratories, with pamphlets describing the facilities for solving problems of applied chemistry. In charge of exhibit: H. L. Sherman and Clarence J. West.

LUNGWITZ CO.

EMIL E. LUNGWITZ—A Kelly filter press, type 150, made of steel and iron, and a type 30 press, made of copper throughout. In charge of exhibit: Emil E. Lungwitz, H. L. Dick and Wm. D. Neuberg.

THE LUNKERHEIMER CO.

MACRELL-EVANS GLASS CO.—Representative samples of laboratory glassware. In charge of exhibit: F. K. Pinckney and J. F. Humez.

MACHINERY UTILITIES CO.

MAGNETIC MANUFACTURING CO.—Magnetic pulley separator for separating iron from various sorts of materials. Type "L", No. 4, magnetic separator for separating iron from brass, aluminum and bronze turnings and other fine material. High intensity laboratory type for separating feebly magnetic materials such as ores, abrasive materials, etc. In charge of exhibit: J. P. Bethke.

MAANN & COOK.

MARLEN, ORTH & HASTINGS CORPORATION—Dyes and intermediates manufactured by the Calco Chemical Co. Processed fish oils for the paint and varnish industries. Tanning oils, melleons and extracts. Samples of results obtained by using these various products. In charge of exhibit: Mr. Breuer and Mr. Johnston.

MARIETTA REFINING CO.—Malachite green; from raw products to finished crystals, some of these weighing 42 lb. each. About 150 different articles dyed or colored with malachite green. In charge of exhibit: H. C. Phelan.

THE MATHIESON ALKALI WORKS, INC.—Caustic soda, soda ash, liquid chlorine, bleaching powder and other Eagle-Head brand heavy chemicals. Solvents, including tetrachlorethane, ethylene chloride and similar products. In charge of exhibit: Adriaan Nagelvoort, Otto A. Fritz and H. D. Winship.

MEAD & CO.—Mead mills. In charge of exhibit: Paul O. Abbe and staff of Paul O. Abbe, Inc.

MERCK & CO.—Emphasis will be placed on the exhibit of medicinal chemicals, particularly those developed since the outbreak of the war, such as bismuth salts, iodine and iodides, salicylates, salol, synthetic oil of wintergreen, etc. Chemical reagents of a high standard of purity.

THE MERRILL CO.—The Nordstrom lubricated plug valve, which is so constructed that, in case the valve sticks, the plug can be lifted from the seat, insuring proper lubrication of the bearing surfaces. In charge of exhibit: C. C. Broadwater, L. D. Mills and S. J. Nordstrom.

METALS DISINTEGRATING CO., INC.—Lead powder for carbon brushes and storage batteries. Tin powder for coated papers and carbon brush industry. Bronze powders for decorative purposes. Aluminum powder for fire works and colorizing. Copper powders for dye works and sherardizing. In charge of exhibit: S. G. Schatzberg.

MINER, EDGAR CO.**MIDWEST ENGINE CO.****MINE SAFETY APPLIANCES CO.**

MOJONNIER BROS. CO.—Mojonnier laboratory specialties: moisture testers, vacuum pumps, viscosimeters, extraction flasks and other laboratory glassware and accessories. In charge of exhibit: T. Mojonnier, J. J. Mojonnier, R. Moon, P. C. Mojonnier and F. D. Courtney.

MONSANTO CHEMICAL WORKS

J. L. MOTT IRON WORKS—Apparatus with acid-resisting enamel such as laboratory antoclaves (one to 5 gal.), crystallizing pans and a complete distilling unit with vacuum still, condenser and container. In charge of exhibit: J. J. Blackmore and R. J. Shively.

NASH ENGINEERING CO.—Nash Hytor air and gas compressors, Nash Hytor vacuum pumps, and Jennings Hytor vacuum heating pumps, assembled and in actual operation and apart for inspection. In charge of exhibit: Irving C. Jennings, Howard M. Wylie, and G. B. Wright.

NASSAU VALVE & PUMP CORP.—"Chemetal" acid-resisting valves and horizontal centrifugal pumps. In charge of exhibit: E. J. Walsh, Henry A. Born, H. M. Pier and A. T. Haviland.

NATIONAL ANILINE & CHEMICAL CO.

NATIONAL FILTER CLOTH & WEAVING CO.—Cotton filter cloth, which is specially constructed for filtering purposes, hence more advantageous to use than ordinary duck. In charge of exhibit: M. W. Smith and Edward Boffin.

NEWARK WIRE CLOTH CO.—A full line of wire cloth, sieves, filter cloths, etc. A high-power microscope will show the construction of patented filter cloth. In charge of exhibit: Alvin Allen Campbell.

NEW JERSEY ZINC CO.—Zinc oxides as used in high-grade paints. Slab zinc (spelter) in various grades, including the well-known "Horse Head" brand. Rolled zinc, lithopone, zinc chloride, sulphuric acid, muriatic acid, salt cake, spie-

geleisen and zinc dust. In charge of exhibit: F. C. Ryan. NEWPORT CHEMICAL WORKS, INC.—The various steps in the manufacture of dyes from "coal to dyestuff" will be shown. In charge of exhibit: John W. Kopf and Giles Low. NIAGARA ALKALI CO.—(See Electro Bleaching Gas Co.).

NIAGARA ELECTRO CHEMICAL CO.

NITROGEN PRODUCTS CO.—Sodium cyanide and other chemicals made by their synthetic process. In charge of exhibit: Adriaan Nagelvoort, H. D. Winship and Otto A. Fritz.

THE NORTHWESTERN CHEMICAL CO.—Synthetic flavors; butyrate, butyl acetate, amyl formate, caproic acid, valeric acid and valerates. In charge of exhibit: Robert L. Wilson and Miss H. M. Allen.

THE NORTON CO.—Alundum and crystolon refractories, laboratory ware and refractory cement, electrically sintered magnesias. Samples of ignition capsules, combustion boats, filtering cones, electric furnace cores, extraction thimbles, pyrometer tubes, and alundum and crystolon for electric furnaces. In charge of exhibit: H. R. Savage.

THE S. OBERMAYER CO.**OHIO POTTERY CO.**

THE OLIVER CONTINUOUS FILTER CO.—A 3-ft. diameter by 2-ft. face Oliver continuous filter in operation, showing distinctive features of this machine. Drum filters, a continuous and automatic Oliver horizontal filter used in products too coarse and fast settling to be handled on the drum filter. In charge of exhibit: R. G. Walker, H. A. Morrison, Paul R. Sheffer and W. Bohlman.

ONTARIO BUREAU OF MINES—Representative samples of ores and minerals from the various mineral areas in the Province, including Cobalt silver camp, Porcupine, Kirkland Lake and Boston Creek gold areas, Sudbury nickel region, etc. Feldspar, fluorspar, graphite, talc and molybdenite from eastern Ontario. Salt and salt products of the Canadian Salt Co. and soda ash from Brunner Mond Canada, Ltd., will be displayed. In charge of exhibit: W. K. McNeill and W. R. Rogers.

ORGANIC SALT & ACID CO.—Thirty Orsac products, including salicylic acid and its salts and derivatives, ortho, meta and para cresotinic acids, triphenyl phosphate, tricresyl phosphate, benzyl alcohol, benzyl benzoate and benzyl acetate. In charge of exhibit: Karl Kolbe.

PALO CO.—Meker burners and furnaces as manufactured by G. Meker & Cie, Paris; Link automatic water still; Hess-Ives tint photometer, the only instrument that will determine color values of liquids and solids by a numerical expression without involving the personal equation; Durieux filter paper; Palo absorber; Lane Laboratory burners, etc. In charge of exhibit: M. J. Seavy.

PARKS-CRAMER CO.—Parks-Cramer hot oil circulating systems. One 200,000-B.t.u. Merrill process system consisting of absorber setting and coil, motor-driven oil-circulating positive pressure rotary pump, thermostatic control apparatus and all necessary accessories. The system will be connected to a Dopp kettle. Guyton & Comfer jacketed pipe fittings. In charge of exhibit: A. W. Thompson, A. B. McKechnie and C. A. Willard.

PENNSYLVANIA SALT MANUFACTURING CO.—Heavy chemicals in large glass containers.

THE PERMUTIT CO.—A small Zeolite water softener for demonstration purposes, and photographs showing installations of various types of water-rectifying apparatus. A complete list of Permutit apparatus displayed on cards and literature describing the apparatus. In charge of exhibit: Albert Tate Smith, Benjamin M. Ferguson, Frank S. Dunham, Class Kennicott, C. A. Roberts and H. G. Taylor.

PERTH AMBOY CHEMICAL WORKS.

LEONARD PETERSON & CO., INC.—High-grade laboratory furniture to exhibit laboratory glassware and apparatus manufactured by E. H. Sargent & Co. In charge of exhibit: Leonard Peterson, O. L. Lethander and Bernard Wiest.

THE PFAUDLER CO.—A 26-gal. utility pot with accessory apparatus; a 6-gal. Milwaukee pot; a 32-gal. Milwaukee pot; a 50-gal. open jacketed tank; a 141-gal. open jacketed evaporating pan; a 500-gal. closed jacketed tank with enameled agitator; a 500-gal. closed tank. All this apparatus lined with Pfaudler acid-resistant glass enamel. In charge of exhibit: R. B. Kilmer, O. I. Chormann, W. E. Foster and H. R. Allen.

THE PHILADELPHIA DRYING MACHINERY CO.—Several working models of "Hurricane" driers for chemicals, clay and porcelain. Also collection of photographs showing installations in representative plants throughout the United States. In charge of exhibit: Walter W. Sibson, C. H. Reumann and H. C. Moore.

PHILADELPHIA QUARTZ CO.—Various grades of manufac-

tured silicate of soda, with literature on the principal uses of each grade as applied. In charge of exhibit: C. F. Wolcott, G. W. Wait and E. A. Russell.

THE PHILADELPHIA TEXTILE MACHINERY CO.—A model of a Proctor four-truck drier for paints, chemicals, colors, etc. A model of Proctor three-conveyor drier for cotton, wool, chemicals, etc. A large display of all kinds of materials dried in Proctor Research Laboratory. In charge of exhibit: E. B. Ayres, Mrs. J. C. Reiter, W. R. Murray, Joseph Tiers and W. J. Dudley.

PNEUMATOR CO., INC.—A working outfit illustrating the simplicity of operation of the pneumator tank gage. Various models will be shown. In charge of exhibit: William Thomas, A. F. Kuehne and Henry Jones.

PRATT ENGINEERING & MACHINE CO.—Photographs of machinery and apparatus manufactured for the chemical and fertilizer trade, and photographs of various plants designed and erected by this company for the manufacture of sulphuric and nitric acids and fertilizers. Designs of plants for the manufacture of acid phosphate and commercial fertilizers and sulphuric acid. In charge of exhibit: George F. Hart, G. A. Austen, E. E. Maher and C. A. Murphy.

PRECISION INSTRUMENT CO.—Carbon dioxide, sulphur dioxide, recorders, indicating draft gages (single, 2 in 1, to 5 in 1), recording gages, calorgraph, gravimeter, coal calorimeter, and other apparatus for testing and measuring gages. The precision CO₂ recorder delivers every 3 min. a definite fixed volume of flue gas, analyzes the mixture and then records on a chart the percentage of carbon dioxide present. It is accurate to within 0.5 per cent. In charge of exhibit: Charles E. Conway.

PRECISION THERMOMETER & INSTRUMENT CO.

PRESSED STEEL TANK CO.

PRODUCT SALES CO.

PROVOST ENGINEERING CORP.

PYROELECTRIC INSTRUMENT CO.—Electrical precision instruments, a-c and d-c galvanometers, electrometers, etc. A new type of lamp and scale reflection indicator, the Northrup pyrovolter, a small Northrup-Ajax high-frequency induction furnace with water-cooled induction coil, in operation. In charge of exhibit: H. F. Porter and W. C. Harter.

QUIGLEY FURNACE SPECIALTIES CO.—Temperature tests on the bonding strength of Hytempite, a highly refractory plastic material for bonding fire brick, etc. Carbosand, a highly refractory fire sand for making rammed-in linings. Insulbrix, a specially prepared cellular insulating brick for furnaces; Quigley powdered coal system for preparing, transporting and burning powdered coal. In charge of exhibit: W. S. Quigley, H. A. Kimber, W. O. Renkin, J. G. Coutant and L. G. McPhee.

RARITAN COPPER WORKS and the ANACONDA COPPER MINING CO.—By-products obtained during the electrolytic refining of copper: White arsenic, tellurium oxide, tellurium, selenium, gold, silver, platinum and palladium, nickel and copper sulphates. Lead from the International Lead Refining Co., East Chicago, Ind., high-grade electrolytic zinc from the Great Falls Refinery, "Anaconda white lead" from the Anaconda Lead Products Co., East Chicago, Ind., products of the new copper rolling mill. In charge of exhibit: S. Skowronski and H. D. Hawks.

RAYMOND BROS. IMPACT PULVERIZER CO.—Four models in operation illustrating the various types of pulverizing mills manufactured by this company, three to be one-quarter size of the actual machines and one full-size model small No. 0000 pulverizer used extensively in the chemical, dry color and dyestuff industries. In charge of exhibit: C. M. Lauritzen, W. M. Cook, S. B. Kanowitz, R. A. Lachmann and W. B. Senseman.

REDMANOL CHEMICAL PRODUCTS CO.—Cigar and cigarette holders manufactured from transparent redmanol. Demonstration of manufacture of molded parts from redmanol molding mixtures. In charge of exhibit: L. V. Redman.

REPUBLIC FLOW METERS CO.—The regular Republic flow meter, together with a recently developed flow meter for making very low differential pressures. This meter measures accurately as low as one-thousandth of an inch water differential pressure. A blower will be installed in the booth so that both meters will be operating under regular conditions. In charge of exhibit: James D. Cunningham, J. M. Spitzglass, C. R. Matheny, C. E. McGregor, J. Tigerman and T. S. Williams.

RESEARCH CORPORATION.

RESEARCH LABORATORY OF CHICAGO.

REVOLVATOR CO.—Models of revolving portable elevators. In charge of exhibit: H. S. Germond, Jr., and others.

ROESSLER & HASSLACHER CHEM. CO.

ROLLIN CHEMICAL CO.

ROSSENDALE-REDDAWAY BELTING & HOSE CO.

SARCO CO., INC.—A complete line of thermostatic steam and radiator traps, metallic gaskets and several models of standard and special temperature regulators. In charge of exhibit: Clement Wells, E. J. Ritchie, F. D. Harger, G. M. Cameron, G. F. Corder and G. B. Burke.

E. H. SARGENT CO.—Laboratory supplies.

SCHAAER & CO.—Chemical laboratory apparatus of American manufacture, including analytical balances, electric flask heaters, etc., manufactured by this company. American-made glassware, porcelain ware and apparatus handled for other manufacturers. In charge of exhibit: Adolph E. Schaar, Eric W. Ohman, Andrew R. Stevenson and J. Gardner Goodwin.

SCHAEFFER & BUDENBERG—Pressure and vacuum gages, mercurial pressure and vacuum gages, gage testers, "Crescent" industrial thermometers, "Reform" mercury thermometers, "Columbia" mercury recording thermometers and other testing apparatus. In charge of exhibit: C. E. George, and Messrs. Parker, Coesfeld and Campbell.

JOSEPH SCHNEIBLE

SCHUTTE & KOERTING CO.—Equipment for handling chemical gases: automatic blowcase attachment, jet pumps, etc., used in handling of chemical liquids. Power-plant valves, spray nozzles, oil-burning equipment. In charge of exhibit: Dr. C. H. Kimberly, A. C. Nell and J. S. Patten.

SCHWARTZ SECTION SYSTEM—A sectional cabinet for filing laboratory chemicals and reagents, samples and specimens. In charge of exhibit: M. P. Schwartz.

SCIENTIFIC EQUIPMENT CO.—(See Central Scientific Co. and Kawannee Mfg. Co.)

SCIENTIFIC MATERIALS CO.—Standard lines of laboratory glassware and porcelain. Complete line of filter papers. Special graduated and blown glassware. The new Fisher burner; museum jars; Scimatco tubing, etc. In charge of exhibit: R. H. Ilix and Dr. F. L. Hincley.

ERNEST SCOTT & CO.—Photographs showing installations made in the following industries: Oil extraction from nuts, seeds, beans, etc., by Scott's solvent process; extraction of grease from bones, packers' tankage, etc.; recovery of glycerine in soap factories and caustic soda from paper pulp spent liquors, cotton mercerizing mills, etc., by the Scott evaporator. Extraction of oil from fish and fish waste, glycol and glycerine refining plants, fatty acid distillation. In charge of exhibit: H. Austin, Robert MacGregor and C. E. Bradley.

SEMET SOLVAY CO.

THE SHARPLESS SPECIALTY CO.—Various models of super-centrifugals featuring centrifugal equipment designed for use in the separation of paraffine wax from mineral oils, together with samples of resulting oils of different crudes. In charge of exhibit: Max B. Miller, F. A. Frank, E. E. Ayres and Walter E. Cox.

SHAWINIGAN ELECTRO METALS CO.

SHAWINIGAN WATER & POWER CO.

SHERWIN-WILLIAMS CO.

B. B. SHIPPERS SUPPLY CO.

THE W. W. SLY MANUFACTURING CO.—A working installation of a "Sly" dust arrester for the collection and reclamation of dust. In charge of exhibit: P. W. Graue and E. J. Moore.

WALTER SODERLING, INC.

SOLVAY PROCESS CO.

SOWERS MANUFACTURING CO.—The construction of Dopp seamless steam jacketed kettles demonstrated by a sawed-up section of a 16-gal. kettle, showing that kettle wall, jacket and staybolts are one single casting with no joints, bolts, seams or welds. A 10-gal. Dopp standard vacuum pan with sweep mixer, 150-gal. Dopp standard kettle with ribbon-type mixer and 350-gal. Dopp rectangular kettle, 8 ft. x 3 ft. 6 in. x 2 ft. deep. In charge of exhibit: R. C. Boggess and P. B. Cox.

D. R. SPERRY & CO.—Filter presses, plates and frames made of various materials, filter press cocks and various plate surfaces. In charge of exhibit: D. R. Sperry and B. H. Conley.

THE STAR BRASS WORKS—General line of spray nozzles in operation. In charge of exhibit: H. D. Binks, B. R. Sausen and C. R. Kranz.

STEIN HALL & CO.

STIMPSON EQUIPMENT CO.

C. H. STÖELTING.

F. J. STOKES MACHINE CO.—Rotary tablet machine in operation making naphthalene balls. Powder-filling machine in operation. Rotary vacuum drier, laboratory vacuum drier, vertical surface condenser, copper vacuum still, automatic water still. In charge of exhibit: L. H. Bailey and C. F. Coleman.

STRESEN-REUTER & HANCOCK, INC.

STURTEVANT MILL CO.—The "Open-Door" line of crushing, grinding, pulverizing, screening, mixing, elevating and conveying machinery. The "Open Door" will be especially featured as a labor and time saver. They swing like the door of a safe and open the interior of their various machines to more complete accessibility than can any number of parts or castings and plates, the removal of which costs so much in time wasted. In charge of exhibit: H. A. Tomlinson, L. N. Doyle, J. S. Vrabek and W. T. Doyle.

SULLIVAN MACHINERY CO.—A model air-lift pumping plant in operation, consisting of Sullivan air-lift pump, separating head, cyclone boosters, etc., electrically operated by compressed air; also samples of its acid pumps, separating heads in standard and special acid and chemical resistant material, and display photographs of installations and equipment. In charge of exhibit: John Oliphant, Howard T. Walsh, Joseph H. Brown, R. E. C. Martin and S. B. King.

SUNBEAM CHEMICAL CO.—Methylene blue, paranitrosodimethylaniline, and acid azo red, eosine, erythrosine, crude glycerine, sulfonated oils, and the dye soap "Rit." In charge of exhibit: L. C. Cates.

SWEDISH CRUCIBLE STEEL CO.—Steel castings for heat-treating processes and for resisting oxidation under high temperature. Complimentary tickets to the Exhibition of the American Steel Treating Society will be issued at this booth. In charge of exhibit: H. H. Harris, Mr. Van Arman and Mr. Kingsley.

SWENSON EVAPORATOR CO.—One evaporator will be in operation, and another so arranged that an examination of the internal construction can be readily made. In charge of exhibit: F. M. deBeers, P. B. Sadtler, P. H. Appell, D. C. Giles, S. W. Hind, A. H. Boehmer and F. F. Mackentepe.

C. J. TAGLIAVUE MFG. CO.—"Tag" P. & W. liquid level and condensate controllers for automatically maintaining liquid levels in evaporators, closed and open tanks, etc. "Tag" self-operating and perfect automatic temperature and pressure controllers for automatically maintaining a uniform temperature or pressure regardless of a variable initial supply in coolers, driers, mixing kettles, stills, etc. "Tag" automatic combination time and temperature controller, the "Tag" absolute pressure controller. In charge of exhibit: Wallace W. White, D. M. Morgan and V. Wichum.

TANK EQUIPMENT CO.

TAYLOR INSTRUMENT CO.—Indicating and recording thermometers and pyrometers; laboratory and oil-testing instruments; pressure and temperature regulators. In charge of exhibit: Messrs. Ely, Amursky, Schwartz, Taylor, Heyss, Pagenstecker, Lemke, Rinder, Levy, Sutherland, Drs. Clark and Hurlbert.

TECHNICAL PRODUCTS CO.

TEXAS GULF SULPHUR CO.—In charge of exhibit: J. A. B. Landell and Arthur S. Cosler.

THE THERMAL SYNDICATE, LTD.—Vitreosil products for laboratory and plant. Vitreosil is unaffected by the usual mineral acids or by sudden and extreme changes of temperature, as will be demonstrated by heating vitreosil crucibles to a temperature of approximately 1000 deg. C. and plunging them immediately into cold water. In charge of exhibit: Stephen L. Tyler and William W. Winship.

THE THERMO ELECTRIC INSTRUMENT CO.—Freas and Thelco types of constant temperature apparatus, forced air and vacuum ovens, also the latest type, the Swirl oven, in which the operator can keep his material in constant agitation while it is subjected to a constant temperature. In charge of exhibit: E. H. Heacock, J. S. LaMer and Royal B. Freas.

ARTHUR H. THOMAS CO.—Kelley electrometric titration apparatus for the determination of Cr, V, and Mn in steel and ferrous alloys. Cain electrometric titration apparatus for the determination of carbon in steel by the direct combustion method. Edwards gas density balance. Volumetric apparatus; electric drying ovens; Mandler diatomaceous filters, etc. In charge of exhibit: R. M. Miller, H. C. Roak and C. C. Roberts.

THWING INSTRUMENT CO.—Recording and indicating pyrometers for all ranges of temperature, paper testing apparatus, particularly basis weight scales, and an instrument for recording the tearing strength of paper. In charge of exhibit: Dr. Charles B. Thwing and William S. Miller.

TITANIUM ALLOY MFG. CO.

TOLHURST MACHINE WORKS—A 32-in. heavy type suspended centrifugal with bottom discharge. Motor-driven 40-in. self-balancing centrifugal. A 20-in. solid curve centrifugal and a new type 12-in. laboratory centrifugal. In charge of exhibit: John S. Gage, T. A. Bryson and T. M. Stuart.

TOWER & WOODEN TANK INDUSTRIAL COUNCIL.—The Council comprises the following companies: Challenge Co., Dunck Tank Works, Eagle Tank Co., Hauser-Stander Tank Co., Johnson & Carlson, U. S. Wind Engine & Pump Co., Wendnagel & Co., Rectangular tank, agitator, generator, film developing, crystallizing, filter tanks, tank with sloping bottom for drainage, model of sprinkler or gravity water supply tank, and burned-in lead-lined chemical tanks, each having a portion cut away so that details of construction may be studied. In charge of exhibit: Engineers of above mentioned companies.

UNITED STEAM PUMP CO.

UNITED SULPHUR CO.—In charge of exhibit: W. N. Wilkinson and W. M. P. Taylor.

UNITED THERMOMETER CO.

UNITED FILTERS—4-1 type American filter with direct motor drive. A No. 2 size Sweetland filter constructed of aluminum, and a small model of a Kelly unit. A small United plate and frame press exhibited for the first time. Samples of cotton and metallic filter cloth for inspection of visitors. In charge of exhibit: C. B. Oliver, J. T. Hoyt and Winslow Southur.

UNITED LEAD CO., the UNITED LINED TUBE & VALVE CO. and the RAYMOND LEAD WORKS.—United lead-lined iron pipe, valves, fittings and tin-lined valves and fittings. A new line of silver-lined valves, centrifugal acid pumps, Uleo hard metal. In charge of exhibit: L. B. Gallison and C. B. Holden.

U. S. BUREAU OF MINES.—Exhibits from the various field offices of the Bureau and safety devices including the army gas mask. In charge of exhibit: M. F. Leopold.

U. S. CAST IRON PIPE & FOUNDRY CO.—Photographs and samples of Uscast products. In charge of exhibit: H. A. Hoffer and J. D. Capron.

U. S. INDUSTRIAL ALCOHOL CO. and U. S. INDUSTRIAL CHEMICAL CO.—Many uses of alcohol shown on an exhibit board. In charge of exhibit: B. R. Tunison.

U. S. STONWARE CO.—Representative pieces of standard chemical stoneware. In charge of exhibit: F. S. Wills and G. M. Wills.

U. S. WIND ENGINE & PUMP CO.—(See Tower and Wooden Tank Industrial Council).

UNIVERSAL OIL CO.**UNIVERSE CO.****VAN SCHAAK BROS. CHEM. WORKS.**

VALLEY IRON WORKS, Appleton, Wis.—A small Vesuvius sulphur burner, a laboratory beating engine and a centrifugal acid-resisting pump. In charge of exhibit: W. H. Burns and R. A. Peterson.

VALLEY IRON WORKS, Williamsport, Pa.—A line of laboratory autoclaves ranging from 23-qt. to 54-gal. capacity and built for operating pressures up to 1000 lb. per sq. in. In charge of exhibit: R. L. Riley and Thomas Senior.

VIRGINIA SMELTING CO.

THE VITREOUS ENAMELING CO.—A full line of Vitreous enameled pans and trays. In charge of exhibit: Harry Warman and Charles E. Bullard.

WALLACE & TIERNAN CO.**WEDGE MECHANICAL FURNACE WORKS.**

WENDNAGEL & CO.—(See Tower and Wooden Tank Industrial Council).

WERNER & PFLEIDERER CO.—Laboratory mixers and grinders. In charge of exhibit: Emil Staehle, J. C. Caley, C. Pletscher, S. D. Gridley, H. Gronbak and H. E. Greay.

WESTERN RESERVE CHEMICAL CO.

WESTINGHOUSE ELECTRIC & MANUFACTURING CO.—Industrial motors and control devices, fans, meters, heating appliances, circuit-breakers and switches.

WHITALL TATUM CO.—Chemical glassware and laboratory apparatus. In charge of exhibit: J. F. Matthes.

J. G. WHITE ENGINEERING CORP.

THE WHITLOCK COIL PIPE CO.—Working model showing the application of exhaust steam in heaters adapted to the chemical industries. In charge of exhibit: R. S. Bull, J. E. Chubb and E. B. Cole.

THE WIDNEY CO.—The Widney modulimeter for testing materials from steel to felt, rubber, paper, leather, etc. In charge of exhibit: S. W. Widney.

WILSON-MAEULEN CO.—Indicating and autographic pyrometers, especially the multiple record tapalog and dust and fume proof pyrometer switches. In charge of exhibit: C. J. Brown, G. V. Nightingale and F. C. Baker.

ZAPON LEATHER CLOTH CO.

ZAREMBA CO.—Photograph and drawings of evaporator installations in many kinds of service in the chemical industries. In charge of exhibit: Edward Zarembo, W. H. Eggert, H. E. Jacoby and B. S. Hughes.

ZAVON, INC.

Natural and Industrial Resources of the North Central States

The natural resources of that group of North Central States comprising Illinois, Indiana, Michigan and Wisconsin are marked by both variety and abundance, as will be set forth in considerable detail throughout this issue of *CHEMICAL & METALLURGICAL ENGINEERING*. Certainly during the war the nation had reason to be thankful for the raw material and finished products which came out of this region.

By means of introduction to the details, which follow, we show opposite an industrial map of the region and give a few tables of condensed information.

The map shows the principal mineral products of the States and gives their relative rank among all similar deposits in the United States.

Table I, showing the mineral production of the Chicago District, was prepared by a local committee of the Chicago Section, A. I. M. E., for use in the souvenir guide book issued for the Chicago meeting of the Institute, Sept. 22-29. Tables II, III, and IV contain data compiled from the U. S. Census of Manufactures and give interesting comparisons on the manufacturing industries of the four States.

The census for 1919, now in preparation, will undoubtedly show a striking increase in all items in the four States.

TABLE II—RANK IN MANUFACTURING INDUSTRIES, 1904-14

	Wage Earners (Average No.)			Value of Products			Value Added by Manufacture		
	1914	1909	1904	1914	1909	1904	1914	1909	1904
	Rank Per Cent. Total	Rank Per Cent. Total	Rank Per Cent. Total	Rank Per Cent. Total	Rank Per Cent. Total	Rank Per Cent. Total	Rank Per Cent. Total	Rank Per Cent. Total	Rank Per Cent. Total
Illinois.....	57.2	47.0	46.9	39.3	39.3	39.3	3.2	38.9	39.1
Indiana.....	92.8	92.8	92.8	83.0	82.0	82.0	8.1	82.9	81.2
Michigan.....	73.9	73.5	83.2	74.5	73.8	72.9	8.2	82.7	73.2
Wisconsin.....	102.8	102.8	102.8	78.9	81.9	82.9	9.2	82.9	92.9

TABLE III—PER CENT INCREASE IN GROWTH OF MANUFACTURING INDUSTRIES, 1899-1914

	Wage Earners (Average Number)			Value of Products			Value Added by Manufacture		
	1904 to 1914	1909 to 1914	1904 to 1909	1904 to 1914	1909 to 1914	1904 to 1909	1904 to 1914	1909 to 1914	1904 to 1909
	to 1914	to 1914	to 1909	to 1914	to 1914	to 1909	to 1914	to 1914	to 1909
United States.....	28.7	6.4	21.0	63.9	17.3	39.7	37.0	15.8	35.5

RESOURCE MAP OF THE NORTH CENTRAL STATES

The figures in the circles show the relative rank among all similar deposits in the United States. Adapted from a complete map of the United States prepared by the Nashville Section, Engineering Association of the South.

Industrial Resources of the Chicago District

Metallurgically, Chicago Ranks Second Only to Pittsburgh as a Producing Center, While in Non-Ferrous Operations Refining and Alloying Are Extensively Represented — Oil Refining and Packing House Products Represent the Most Extensive Chemical Interests

Non-Ferrous Metallurgy in the Chicago District

BY H. B. PULSIFER

NOT infrequently we have asserted and defended the statement that Chicago is the very greatest metallurgical center on the globe. Pittsburgh with its pre-eminence in iron and steel has to be considered, but with Pittsburgh the argument largely ends with the great iron and steel plants; Chicago comes second in iron and steel, but its real claim to greatness is in the abundance and variety of the non-ferrous metallurgical plants.

In the Chicago district one finds 35 great plants of prime importance, as well as over 200 foundries. In 1917 the author, with his students at Armour Institute of Technology, undertook a sort of census of these foundries in the Chicago district. It was desired to check up the current lists of plants, note the sort of work and equipment at each, the number of men employed as well as the presence of technical men, and the attitude toward using graduates. The results were amazing: plants employing a thousand or more men had never before come to our attention. The range of work surprised one: every stage from antipathy to full use of technical talent had several representatives.

In order to present a clear idea of the varied metals and processes one will discover in the Chicago district, the accompanying two lists have been prepared. List I arranges the more notable plants according to the metal handled or produced. List II groups the more conspicuous plants according to the sort of operations performed, such as smelting, refining or electroplating

It is frankly admitted that the lists are incomplete; in fact, the author has never started out on a metallurgical exploring trip about the great inland metropolis without abundant discoveries as to plants, metals and processes.

Surprisingly large and diversified amounts of ores and concentrates come to Chicago for treatment. Instances of this sort have been Butte zinc concentrates and Wisconsin zinc concentrates for roasting, Boss platinum ores from Nevada, lead concentrates from Wisconsin, antimony ores from South America, gold bullions from cyanide plants, lead bullions from Mexico, sweepings from the United States and Canadian mints.

CHICAGO PRE-EMINENT IN SECONDARY METAL RECOVERY

It is in the secondary metal recovery, however, that Chicago probably ranks as pre-eminent. This business amounts to many millions of dollars a year. Scrap and junk metal is reclaimed in the usual furnaces and by similar processes as virgin metal, again going on the market indistinguishable from metals and alloys direct from ores. The abundance of almost every sort of scrap metal makes it profitable to make brass, bronze, solders, babbitts and various other alloys from reclaimed stock, possibly adding some fresh stock to bring to specification. One dare not say that gold bars from sweepings are less pure than bars from cyanide mills or that brass from scrap copper trolley wire is inferior to brass from new electrolytic ingots.

Certain of the Chicago plants are always doing interesting and notable work. The Western Electric Co., Crane & Co., the Great Western Co., Goldsmith & Co.,

SKYLINE OF CHICAGO—GRANT PARK IN THE FOREGROUND

FIG. 1. THE UNITED STATES METALS REFINING PLANT AT EAST CHICAGO

the International Lead Co., the United States Co., the International Harvester Co. and the National Lead Co. may each have a dozen furnaces on the most varied work. Oxide copper furnaces are at work just as they used to be in Arizona during the '80s, and the slags are high in copper, too. Small copper reverberatories are getting out tough pitch copper just as the big furnaces do at Great Falls and Perth Amboy. Lead blast-furnaces are making bullion and matte just as they do in the West; one of the neatest bag houses is right in the heart of the city, and another fine example is at East Chicago.

It can hardly be held that much of the plant work is less metallurgical because it is joined up with metal

preparation and manufacturing processes. Most of the Chicago plants add to the smelting, refining, graining and shaping of the metals also the final factory operations which put the stock on the market for ultimate consumption. Thus the Goldsmith plant is fundamentally a precious-metal plant, but the company is also widely known as furnishing dental specialties. The National Lead Co., with all its furnaces, alloying and extrusion work, is better known as supplying pigments

LIST I—METALS PRODUCED, REFINED AND PREPARED IN THE VICINITY OF CHICAGO

Iridium	Goldsmith Bros. S. & R. Co.
Palladium	Goldsmith Bros. S. & R. Co.
Platinum	Thomas J. Dee & Co.
Gold	Goldsmith Bros. S. & R. Co.
Silver	Goldsmith Bros. S. & R. Co.

FIG. 2. THE INTERNATIONAL LEAD REFINING CO.'S PLANT AT EAST CHICAGO

and paint. The Grasselli Chemical Co., with its roasters and metal dissolving facilities, is known rather as supplying acids and salts. A certain large manufacturing jeweler employing 50 or 60 men in a corner of one floor of a huge office building is apparently only busy at making rings and pins and setting precious stones, but really he is even more fundamentally interested in alloying, deoxidizing, hardening, shaping, electroplating and reclaiming scrap and sweepings. The International Harvester Co. makes and sells farming implements, but we would consider it a rather large metallurgical plant which operates 4 cupolas, 8 air furnaces and numerous brass furnaces.

THE UNITED STATES METALS REFINING CO.

The United States Metals Refining Co. has possibly the most important and interesting plant near Chicago, excluding the steel plants. This is an electrolytic lead refinery; base bullion from the West is the chief raw material, electrolytic lead and pure bismuth are the two chief finished products. The precious metals in the form of doré slabs are sent to Chrome, N. J., for final separation and purification. Besides the immense tank house and remarkable electrolytic work, the plant produces hydrofluoric acid and hard lead alloys. In the recent death of William Thum, long superintendent of the plant, not only the community loses a strong and able character but the metallurgical world a penetrating investigator and constructive scientist. The plant has accomplished much in the refining of lead, the treatment of the electrolytic slime and the winning of the very purest bismuth. Our view of the plant in Fig. 1 shows the immense tank house in the rear with the (from the right) office, fluosilicate building, bag house and blast-furnace building across the foreground.

THE INTERNATIONAL LEAD REFINING CO.

The International Lead Refining plant was built at East Chicago under the direction of George Hulst, a very capable manager in the lead refining business. This is the most modern of the world's lead refineries using the Parkes process. It is the lead refining department of the Anaconda Copper Mining Co. At the

right in Fig. 2 one sees the striking bag house, while the main furnace building is at the left. The plant has never really been pushed to capacity and is designed for expansion to much larger size. Besides operating it at remarkably efficient cost, Hulst has done much interesting work in smelting antimony ores for the hard-lead trade.

The Goldsmith plant is possibly the most versatile in the whole district. Precious metal values are recovered from concentrates, ores, residues and sweepings by sintering, smelting and the Parkes process of desil-

FIG. 3. THE GOLDSMITH BAG HOUSE, 58TH AND THROOP

verization. Precious metal parting is performed by acids and pure iridium, palladium, platinum, silver and gold are produced. Iridium is marketed as powder or in hard platinum, but the other metals are melted and sent out in bars, rolled plate, granulated or as salts. A unique copper-dissolving tank used in the manufacture of blue stone, a model bag house (Fig. 3) and improved chemical laboratory were features designed by the author. The plant manufactures a splendid line of dental cements, largely the product of an Armour Institute graduate. Osmic acid, silver chloride and silver nitrate, gold chloride and blue stone are further plant products. Fig. 4 is a view in the melting room; 18-in. dishes for parting gold bullions are on the table and a wheelbarrow of silver is at the right. The silver is melted in the crucible furnace at the right and the parting done in

the oven behind the two men. The diagram of the plant as given in Fig. 5 indicates the spread of the plant; it has recently been largely rebuilt.

GREAT WESTERN SMELTING & REFINING CO.

The Great Western Smelting & Refining Co. plant is equipped with machines for grinding, washing and briquetting metallic residues. There is one cupola, or blast-furnace, and reverberatories for matte, solder, lead, brass, copper and copper refining. There are eight pit furnaces for crucibles, a sweating furnace and three large melting kettles. Precious metal residues are not handled, but otherwise the plant reclaims most of the non-ferrous wastes of civilization and turns out a long list of metals and alloys. An adequate laboratory enables work of precision to be done.

LOCATION OF THE MORE PROMINENT METALLURGICAL PLANTS IN THE CHICAGO DISTRICT

FIG. 4. VIEW IN THE MELTING ROOM AT GOLDSMITH'S

THE THOMAS J. DEE PLANT

The Thomas J. Dee plant is on the North Side of Chicago, a small heavily barred strong-box for precious metal work. Furnaces are installed for melting and refining the precious metals, while the acid process is used for parting. Besides turning out bars and slabs, the plant features drawing precious metals into wire. After the short, thick rods are cast they are swaged down and then drawn through dies to specified size. Gold, silver, platinum and their alloys are thus treated for the market.

It is obvious that Chicago is a great lead refining center and a heavy producer of the precious metals,

either pure or alloyed. It is also a conspicuous center for the antimony-lead alloys, bismuth, the copper and tin bearing metals, and solders. A large portion of this business comes through the smelting, refining and alloying of junk materials.

The most conspicuous voids in the general metallurgical field result from the absence of much virgin ore reduction, leaching operations, electrolytic copper refining and zinc smelting. For the electrolytic copper refining one must go far, either West or East, but for the zinc smelting a short trip to LaSalle and DePue puts one among the greatest plants.

School of Mines,
Butte, Montana.

FIG. 5. DIAGRAM OF THE GOLDSMITH PLANT; MORE RECENTLY MUCH REBUILT AND IMPROVED

Chemical Industries of Illinois and the Chicago District

BY PROCTER THOMSON

THE fortunate geographic location of Chicago has led to the development of a wonderful system of transportation facilities. This consists not only of the numerous railways which radiate from Chicago in every direction, but includes the various belt lines and clearing yards which facilitate the movement of goods from one railroad to another. The coal fields of Illinois and Indiana insure a plentiful and sure supply of fuel at low cost. When Eastern cities are tied up with freight congestion, Chicago has found it possible to obtain raw materials and fuel and to ship finished goods. The appreciation of these factors is leading to the development of Chicago as an industrial center. This development has extended beyond the border of Illinois and over into Indiana. As these northern Indiana industries are in the Chicago district, they will be considered here instead of with Indiana industries. Chemical industry has taken part in this growth in a greater degree than is generally known.

The chemical industry of Illinois other than the Chicago district is considerable. It participates in the transportation advantages of Chicago, but is generally the result of nearby sources of raw material. This is particularly the case of the zinc industry with the associated acid plants.

BY-PRODUCT COKE PLANTS

Illinois has unlimited supplies of limestone and fluorspar, which, in addition to the factors already named, contribute to the growth of the iron and steel industry, which has reached great proportions and is still growing.

The Interstate Iron & Steel Co. has four open-hearth furnaces at South Chicago.

Closely associated with iron and steel is the by-product coke industry. This has reached tremendous proportions. The United States Steel Corporation has 700 Koppers ovens at Gary and 280 Koppers ovens at Joliet. The total coking capacity of these ovens is 12,000 tons of coal per day.

The By-Products Coke Corporation operates 280 Semet Solvay ovens at South Chicago and has 120 more nearly ready to operate at Indiana Harbor. The combined capacity of these 400 ovens will be 45,000 tons of coke per month.

MISCELLANEOUS METALLURGICAL INDUSTRIES

Most of the metallurgical activity in the Chicago district other than iron and steel is in the refining of trade wastes. There are notable exceptions to this, however. One of these is the Fansteel Products Co. This company at North Chicago is producing metallic tungsten, molybdenum, and cerium of great purity. The tungsten is produced from wolframite, and the molybdenum from ammonium molybdate or molybdic oxide. The processes are practically the same for both metals. The raw material is fused with sodium carbonate, the soluble salts of the metals leached out, and by alternate precipitation with acid and solution in alkali, with the accompanying filtering and washing, oxides of a high degree of purity are produced. After ignition the oxides are reduced by hydrogen. The metallic powder is pressed into bars

and sintered electrically. These bars are then swaged into the desired shape. The tungsten is cut into discs and mounted on the proper supports for electrical-contact apparatus. The molybdenum is used in the manufacture of spiders for tungsten filaments. Metallic cerium is produced from materials obtained from the Lindsay Light Co. A pure cerium chloride is made which is fused and electrolyzed and metallic cerium recovered. This is used in pyrophoric alloys.

PAINT PIGMENT

The manufacture of paint pigments is carried on at a number of plants in Illinois. Lithopone is manufactured by Sherwin-Williams at Pullman, the Midland Chemical Co. at Argo and the Consolidated Chemical Products Co. at Alton. The Sherwin-Williams Co. manufactures corroded white lead and dry colors, including prussian blue, chrome yellow and para toners.

The National Lead Co. has a large plant producing corroded white lead by the old Dutch process, red lead and litharge. Here also, babbitts, solder and metals for tempering baths, etc., are produced.

The Carter White Lead Co. produces white lead in South Chicago.

HEAVY AND INORGANIC CHEMICAL MANUFACTURE

The field of heavy and inorganic chemical manufacture is well taken care of by Illinois and the Chicago district. The General Chemical Co., with factories at South Chicago, Chicago Heights and East St. Louis, manufactures a general line of heavy chemicals, including mineral acids, sodium sulphide, zinc chloride, silicate of soda, aluminum sulphate, soda alum and contact sulphuric acid.

The Grasselli Chemical Co. manufactures heavy chemicals at East Chicago.

The Central Chemical Co. at West Hammond, Ill., produces brimstone sulphuric acid, hydrochloride acid and nitric acid.

One of the most interesting developments in Chicago is the Lindsay Light Co., which originally was a producer of incandescent mantles for gas lights, but market conditions in 1914 led it to become a producer of the basic materials used in the mantle industry. The raw material used is monazite sand from India. From this the company is producing thorium nitrate, cerium salts and titanium potassium oxalate. It is almost alone in this field. Beryllium and antimony salts are also being produced. Since the signing of the armistice it has been preparing for the production of dyestuffs and will soon be in the market with phthalic anhydride, phenolphthalein, methylene blue, fuchsine and other products of like nature.

Most people think of borax as being produced in the region where raw materials are found. The Thorkildsen-Mather Co., however, finds conditions in Chicago so favorable to chemical industry that it has located its factory here. It produces borax in the stockyards district from California colemanite.

The production of radium compounds is also being carried on in Chicago—the Carnotite Reduction Co. is producing radium bromide and vanadium compounds from Colorado carnotite.

The Superior Chemical Co. at Joliet is making filter alum, cream of tartar substitute and soda alum, using Arkansas bauxite. Located near by is the Superior Phosphate Co., manufacturer of calcium phosphates.

Stiesen-Reuter & Hancock are producing metallic

salts and soaps of lead, manganese, cobalt, iron and zinc, also aluminum salts and calcium and magnesium stearate and oleate.

The Chicago Copper & Chemical Co. produces barium salts, glauber salts and sodium sulphide.

The Victor Chemical Co. has a large plant at Chicago Heights. Among other products, the company manufactures at the present time monocalcic and dicalcic phosphate, monosodium and disodium phosphate, mono-ammonium and di-ammonium phosphate, phosphoric acid, epsom salts, sulphuric acid and oxalic acid. Oxalic acid is one of the latest additions to its line and is made by the synthetic process, which is claimed to produce an acid of superior strength and purity.

The Dearborn Chemical Co. has found Chicago a most convenient place to build up an extensive business

in their opinions as to the advisability of certain chemical manufactures.

Armour & Co. manufacture anhydrous ammonia, soap, glue, glycerine, fatty acids, animal fertilizers (tankage, bone meal), acid phosphate and rock phosphate. They refine and hydrogenate oils for lard substitutes, etc.

Morris & Co. make anhydrous ammonia, glycerine, fatty acids and refined and hydrogenated oils.

Swift & Co. manufacture soap, glycerine, fatty acids, glue, acid phosphate and mixed fertilizers, refined and hydrogenated oils, and oxygen.

The chemical activities of Wilson & Co. are confined to refining and hydrogenating oils, manufacturing fertilizers and glue.

Abattoir pharmaceuticals are manufactured by

GREAT WESTERN SMELTING & REFINING CO. PLANT

in boiler compounds and water treatment. It is also manufacturing an interesting rust inhibitor, which consists of a petrolatum-like product with the rust-inhibiting compounds emulsified therein.

The Illinois Match Co. has a factory at Joliet.

The Illinois Glass Co. has a large plant at Alton and a small one at Chicago Heights, Ill., for the production of bottles. The glass at the Alton plant is produced by the continuous process. New equipment has been developed for this plant for the machine blowing of very large bottles.

PACKING-HOUSE CHEMICAL INDUSTRIES

The location of packing-house interests in Chicago has led to the growth of extensive chemical manufacturing along the lines of soap, glue, glycerine, fertilizers, etc. All of the packers are working with cottonseed, soya bean and other vegetable oils in addition to the fats. It is interesting to note that not all of the packers do the same things. They appear to differ

Armour & Co. and by the Hollister-Wilson Co., which has just completed a new plant. Both firms manufacture digestive ferments, organic extracts and organo-therapeutics.

There are a number of soap manufacturers in Chicago who operate independently of oil or fat manufacture. Typical of these are Fitzpatrick Bros., James S. Kirk & Co. and the Allen B. Wrisley Co.

Similarly situated are glue and fertilizer manufacturers who purchase their raw materials from various sources. The United Chemical & Organic Products Co. at West Hammond, Ill., manufactures gelatine, glue, fertilizers, etc.

Chicago has a great number of tanners. Most of them are conducting operations by rule-of-thumb methods, so they cannot really be classed as chemical industries.

Not to be classed as a packing-house activity but closely associated in character is cottonseed oil refining. The American Cotton Oil Co. and the N. K.

Fairbank Co. have a large plant in Chicago for the refining of oils. Their principal source is the cottonseed oil from their own mills in the South. Here they refine and hydrogenate cottonseed and other vegetable oils and distill fatty acids, producing soap products, glycerine, lard compounds, cooking oil and salad oil. It is especially interesting to note that the American Cotton Oil Co. has established a research department which is on an equal basis with the production department and sales department. Research for all of the plants is carried on here.

MISCELLANEOUS ORGANIC INDUSTRIES

The Corn Products Refining Co. has a large factory at Argo. Here it produces starches, dextrines, corn syrup, corn sugar and corn oil for industrial purposes, as well as salad and cooking oil.

The Redmanol Chemical Co. produces its anhydrous phenol resin. Using this as a base it molds a great variety of products ranging from cigar holders to electrical insulating materials. It has recently perfected a cold molding compound.

The Abbott Laboratories was originally a producer of alkaloids for medical use. In addition to the extraction and purification of alkaloids it now manufactures a number of synthetic organic pharmaceuticals. These include the Dakin antiseptics—chlorazene, dichloramine T, chlorocane (a solvent for dichloramine T) and

oil is refined at its central refinery and various grades of benzol, toluol, solvent naphtha, etc., produced. Ultimately the company plans to have its own by-product coke ovens.

The Barrett Co. has a plant in Chicago for the refinery of coke-oven tar. Here it separates the pitch, light oil and heavy oil. Further refining of the light oil into benzol, etc., is taken care of at Eastern plants of the company.

Chicago has a number of rubber manufacturers. The Inland and the Century Rubber companies produce tires. The United States Rubber Co. (the Mechanical Rubber Co.) has a large plant producing belting, hose and molded soft rubber goods. The Dryden Rubber Co. produces molded goods and auto tubes and is contemplating engaging in the manufacture of tires.

The Essenkay Products Co. produces rubber substitutes—vulcanized oils—which are used in the rubber trade as well as for erasers, tire fillers, bath sponges, etc.

The field of dyestuffs is covered by three plants in Illinois in addition to the Lindsay Light Co., already mentioned. The Sherwin-Williams plant at Pullman is producing a great many of the dyes and intermediates formerly imported. Among the products are beta naphthol, mono-acid, Schaffer salt, R salt, G salt, Tobias acid, trisulphonic acid, acet-toluide, anthranilic acid, ponceau 5 R, lake orange B, lake red D, lake red

PLANT OF THE CORN PRODUCTS REFINING CO

halazone. It is also producing procaine (novocaine) and dimethyl barbituric acid (veronal).

Burke & James sensitize photographic paper and films.

The Carus Chemical Co. in La Salle, Ill., manufactures saccharine, chloramine T and potassium permanganate.

An interesting plant, which has duplicates at other points in the United States, is the carbon dioxide plant of the Liquid Carbonic Co. Here power is obtained as a by-product. Coke is burned under boilers, the flue gas is scrubbed with water and absorbed in alkaline solution in large absorbing towers. The solution is then heated, the CO₂ driven off, collected, and compressed to 1000 lb. per sq.in. in cylinders. The steam produced by burning the coke runs the compressor and leaves a surplus for other purposes.

The Peoples Gas Light & Coke Co. has installed four light oil reclaiming plants to save the benzene, toluene, etc., produced in its water gas plants. The recovered

C, scarlet 3 R, scarlet 2 RR, naphthol yellow S, pigment scarlet 3 B, orange GG, alizarine yellow GB, alizarine yellow G, alizarine yellow RW, alizarine brown 3 R, alizarine brown B, crocein scarlet, orange Y, brilliant orange 4 GR, scarlet 2 RG, fast red TEX, fast red A, fast red 3 BX, fast red 6 BX, lake red P pulp, litho fast orange O, graphic red R pulp, graphic red Y pulp, brilliant crimson No. 10, chrome black B, chrome black JB, acid claret B, fast acid milling black, methyl violet, paraphenylenediamine, ursol DB, ursol P, leather brown, fuchsine X, XX, XXX, XXXX, fuchsine crystals, alkali blue, spirit blue, soluble blue. It has also an acetic acid plant.

The Monroe Color & Chemical Co. at Quincy was forced into dyestuff manufacture to keep up a flourishing package dye business which had been built up on imported material. It is now making H acid, benzidine, dinitrobenzene, metaphenylene, diamine, benzo blue BB, navy blue, diamine green, brigot green, benzo orange, benzo purpurine and Monroe direct black, and

is able to supply its own needs and have a surplus for sale.

Dicks, David & Heller, at Chicago Heights, have been manufacturing since July, 1917, starting with fuchsine. They are now making fuchsine crystals, alkali blue, soluble blue, water blue, phosphine, malachite green and metinol yellow and are having success in foreign markets formerly filled with German products.

The Special Chemicals Co., Highland Park, was organized to produce certain unusual chemicals practically unobtainable in this country since the war. Among its products are a number of the rare bacteriological sugars and their alcohols such as inulin, galactose, levulose, xylose, dulcitol and mannitol. The company maintains a research department and expects constantly to add to the list of sugars now available. It also manufactures such chemicals as dimethylglyoxime, nitroso-beta-naphthol, cupferron, potassium cyanate and chemically pure uric acid. The raw material for this last named product was formerly sent from this country to Germany, manufactured there into pure uric acid, and subsequently resold in this country. It is just this condition of affairs that Special Chemicals Co. hopes to help correct.

Several firms whose main line is far from chemical have gone into chemical manufacture to fill special needs.

Sears, Roebuck & Co. have a paper mill with a capacity of 17 tons per day. Its waste paper furnishes the raw material for the production of paper suitable for wall paper. Mineral pigments are made, and organic lakes precipitated for wall paper colors.

The Western Electric Co., while not ordinarily considered in speaking of chemical manufacture, is conducting chemical operations of considerable magnitude and interest. This company has an extensive hard rubber department manufacturing rod, sheet, telephone receivers, etc.; a metal finishing division doing plating, sherardizing and Bower-Barff work; and a cable sheathing department producing about 40,000 tons of lead alloys per year. The production of ceramic insulation has been started and is likely to develop to considerable proportions. The most interesting development, however, is the refining of iron electrolytically. The plant for this purpose produces about seven tons per week. So far as known this is the only commercial plant in operation in the United States.

REFINERIES

Two refineries are located in the Chicago-Gary district, that of the Standard Oil Co. at Whiting and that of the Sinclair Refining Co. at East Chicago. The Whiting plant has a capacity of 35,000 bbl. of crude petroleum per day and the East Chicago plant of 6500 bbl. The crude petroleum is pumped direct from the Mid-continent field through two pipe lines that enter Illinois just north of Keokuk, Ia., and lead directly to these two refineries. The usual great variety of refinery products originate here, and the plants are interesting rather on account of the scale of their operation than because of unusual methods and equipment.

CLAY PRODUCTS

In the 24 ceramic plants in Cook County, Illinois, and the one in Lake County, Indiana—the two counties in which the Chicago-Gary district is included—well

over \$5,000,000 worth of brick and tile products and about \$200,000 worth of pottery products, making in all a total of more than \$5,500,000 for the ceramic industries, are manufactured. Common brick makes up somewhat more than half of the total value and architectural terra cotta, fireproofing, drain tile, floor tile, red earthen ware and sanitary ware are among the many other varieties of clay products manufactured in this district.

The North Western Terra Cotta Co. has the only terra cotta plant in the district. Ordinary clays from Indiana and crucible clays from all over the United States go into their 25,000 tons of terra cotta and the 100,000 high-grade smelting crucibles produced annually.

The Harbison-Walker Refractories Co. of East Chicago is equipped to make 100,000 silica brick daily. Its raw silica is quartzite from the Devils Lake (Baraboo) district of Wisconsin.

The abundance of ordinary raw clays in the surrounding district, the ease with which fuel and special raw materials are obtainable, and the large and growing market afforded by the industries and large population make of Chicago and its vicinity an admirable location for ceramic industries.

STONE, SAND AND GRAVEL

About \$2,000,000 represented the value of stone produced in Chicago and immediate vicinity for 1917 and about one-third of a million dollars was the value of the sand and gravel.

Just about one-half the stone was used for concrete and about one-tenth for flux. Rubble, riprap, road making, railroad ballast, flux and fertilizers make up the uses of the remainder. Practically the whole of the million tons of sand and gravel produced in 1917 went into construction work.

One of the largest quarries for crushed stone in the Chicago district is that of the United States Crushed Stone Co. at McCook, about one mile west of Summit. Unusual features in machinery, equipment and methods of production make this plant of exceptional interest to other producers everywhere and to consumers of crushed rock.

SUMMARY

It is hoped that the reader will get some idea of the number and magnitude of the problems of chemical industry that are being solved in this region. Great as the development has been, it is only a beginning. Unequalled transportation facilities, a plentiful supply of fuel, space for development without a limit and a wonderful agricultural region to feed industrial populations are economic forces that are all working in favor of this district.

A dependable estimate of the total value of the industries in the Chicago-Gary district would be exceedingly difficult if not impossible to make. However, statistics are available which go to show that in Lake County, Indiana, and Cook County, Illinois, the value of the stone, lime, sand and gravel, clay products, mineral paint, pigments, cement, coke and steel reached easily the \$300,000,000 mark in 1917. If statistics for the inorganic chemicals, the refinery products, the metallic products outside of steel and a number of smaller industries that could be classed as mineral were included, who knows but the estimate would be double?

Iron and Steel Plants Near Chicago

BY ERNEST EDGAR THUM

GARY comes first to mind when thinking of ferrous metallurgical plants near Chicago, but it should not be forgotten that many years before Gary was planned a very large and modern plant was operated at South Chicago by the Illinois Steel Co. Perhaps it was a knowledge of the operating cost and technical results attained at South Chicago which impelled the big men of the Steel Corporation to locate the huge Indiana Steel Co. and its affiliated operations a few miles southeasterly on Lake Michigan. Half way between point of origin of Pennsylvania coal and Lake Superior iron ores, closely adjacent to tremendous bituminous fields in the North Central States, with ample fluxes and refractories close at hand, with a large industrial center near by to use as a labor reservoir, in the center of wide agricultural districts to be used as a food store, served by unexampled railroad facilities and by water transport second only to a highly developed ocean port, this situation is well nigh ideal for large-scale operations in steel.

The South Chicago works of the Illinois Steel Co. are somewhat congested and lack orderly arrangement owing to the fact that the company started many years ago and built its plant as the demand for its products increased. However, the concern is officered by men of most progressive ideas, and its metallurgical practice has always been of the best—witness the fact that it was the pioneer in the production of electric steels in quantity, and has recently developed the triplex process—converter to open-hearth to electric—to a large-tonnage commercial success.

The company's plants at Chicago, Joliet and Milwaukee include 17 blast-furnaces, 8 converters, 35 open-hearth, and 3 electric furnaces. Its pig iron is largely consumed in its own steel making operations, whose ingots are rolled in 26 rail, merchant, bar and structural mills, eventually finding a market as rails, sheets and shapes. Its rail mills are especially noteworthy, being equipped with every possible labor-saving device—indeed, the rolling of the heavy rails required by American roads would be utterly impossible without most adequate mechanical handling equipment.

MECHANICAL HANDLING OF ORE AT GARY

Mechanical handling, especially of incoming ore, is utilized to the fullest extent at Gary. The methods are indeed not unique, but well repay study by one not familiar with modern methods in getting a heavy raw material like iron ore from a huge lake steamer into bin or stockpile. From the time the iron enters the plant as ore until it leaves as shape or billet, it is treated by mechanical and metallurgical equipment installed on a grand scale. The engineers who planned the Gary works were indeed fortunate in being able to start from the ground up, in having almost unlimited money at their command, and the best technical talent as associates. In this way they were able to plan not a series of departments but a huge machine, each part so designed to fit into its neighbor with the smoothest mesh and least lost motion.

Statistics of this largest of steel plants are more or less dry reading. Twelve blast-furnaces, 46 open-hearth steel furnaces, 14 blooming, rail, plate and merchant mills, a 560-retort coke plant and a list of the

auxiliary departments would not give any comprehension of the magnitude of their operations.

Near by are associated a large number of steel-using manufacturing establishments, such as the closely affiliated American Bridge Co. While structural fabrication is somewhat foreign to metallurgy, still this company's excellent forge and annealing equipment will be of interest to those not attracted by the systematic way a large column or girder is assembled from a score of miscellaneous pieces. Seven high-speed steam-hydraulic presses are used in forging bent pieces, ranging in capacity from 150 to 3000 tons, the latter capable of turning out solid or hollow forgings weighing up to 50 tons. Twelve annealing furnaces of modern design make up the equipment in this department.

OTHER STEEL COMPANIES

At Indiana Harbor, the Inland Steel Co. has two modern blast-furnaces in operation, one of which is interesting in that it ran 5 years on its last lining, producing approximately 1,000,000 tons of pig. Molten iron is delivered to twelve 60-ton basic open-hearth furnaces, and the resulting steel ingots are rolled in a 36-in. blooming mill and a variety of smaller mills to a number of different shapes. Production at this plant approximates 1,000,000 tons of steel per annum, exclusive of the tonnage of small sections which have been produced at its Chicago Heights works since 1893.

In this same vicinity (South Chicago) the International Harvester Co. operates 3 blast-furnaces, with a yearly production of 450,000 tons of pig iron, a bessemer converter and a 35-in. blooming mill, 3 merchant bar mills and a shafting mill with a combined output of 350,000 tons of finished shapes.

The Mark plant of the Steel & Tube Co. of America, at East Chicago, has only one blast-furnace, capacity 600 tons, but this is the largest in the country, being 15 per cent greater than any other. Steel is produced in open-hearth furnaces and is principally made into plates. The 30-in. universal plate mill holds a record for rolling more than 17,000 tons of plates in a month. The main mill tables are designed to shear plates. The mill is served by four 4-door regenerative heating furnaces.

This completes the list of steel companies which produce iron direct from ore in blast-furnaces. Several other concerns in this vicinity operate open-hearth furnaces, using scrap, cold pig and ore as their iron-bearing materials, while others, such as the Republic Iron & Steel Co. at East Chicago, produces a very sizable tonnage of merchant shapes from fagoted scrap.

ALLOYS AND CASTINGS

Among several companies, each of which deserves special attention, not possible in such a brief résumé of the subject, may be mentioned the three plants of the Interstate Iron & Steel Co., at South Chicago, Grand Crossing and East Chicago, specializing in alloy steels; the Hubbard Steel Foundry Co., at East Chicago, notable for high quality steel castings; the American Steel Foundries Co., and Standard Forgings Co., at Indiana Harbor, with a combined monthly output of 13,000 tons of car and locomotive parts and axles.

The Crane Co. operates two bessemer converters and one electric furnace; it is the largest manufacturer of valve iron in the world and during the war handled 700 tons of iron and steel a day in its three Chicago plants.

Natural and Industrial Resources of Indiana

A Description of Some of the Mineral Resources and a Review of Some of the Chemical Industries of Indiana—Importance of the State's Organic Chemical Plants and of the Work in Their Research Laboratories

Raw Material Resources of Indiana

By W. N. LOGAN, PH.D.
State Geologist

FROM a commercial standpoint the ideal State would be the one whose resources permitted it to supply its own needs. But it is a fact well established that no State lives to itself alone. But if during a world cataclysm such as we are experiencing an impenetrable barrier should be built about Indiana, the diversity of her natural resources and her manufacturing industries would enable her inhabitants to go forward toward the goal of self-preservation and self-realization. For Indiana has been favored with natural resources the variety, value and abundance of which are not realized by a large part even of her own citizens. In case of extreme isolation, Indiana could produce for her own needs enough coal, petroleum and its products, gas, iron, building stone, lime, cement, salt, fertilizers except phosphate, paint pigments, mineral dyes and by an expensive process aluminum. She would be without copper, nickel, lead, zinc, silver and platinum, though she could probably produce enough gold for front teeth filling.

The advance made in the utilization of some of these resources has been rapid, yet after more than a century of existence as a State many of its mineral resources remain latent or only meagerly developed.

FUEL

Because of the dependence of manufacturing and industrial development on fuel, this resource is of primary importance, and Indiana's possessions in coal, petroleum and natural gas place her in a position of great economic independence. Of coal, Indiana produces annually its five tons per capita, the per capita consumption of the United States, and a surplus of nearly two and one-half million tons. The coal beds of Indiana occupy an area of approximately 7000 sq.mi. in the western and southwestern parts of the State. One or more beds underlie the whole of sixteen counties and parts of ten others. According to Ashley the total amount of coal in Indiana approximates 50 billion tons.

Of this amount more than 13 billion tons is workable. The total amount which has been mined is about one-half billion tons. Approximately 17½ million tons are being mined each year, with a yearly increase between ½ and ¾ million tons. The coals of Indiana rank well among the bituminous coals of the Interior basin. They contain a high moisture and volatile matter content and only a medium ash and sulphur content. Although belonging to the bituminous division, they contain a variety of high fuel value for domestic use called "block" coal because its laminated and jointed condition causes it to break up into large blocks; also a variety of cannel coal, which is a good gas producer. There are more than thirty beds of coal, nine of which are workable. The average thickness of the vein known as No. 5 is about 5 ft., and a maximum thickness of more than 10 ft. has been recorded. Indiana ranks sixth in the production of bituminous coal. One of its mines holds the world's record for the production of bituminous coal from one mine in a single day. The American mine located at Bicknell, Knox county, on Feb. 8, 1919, mined and loaded 6128 tons on 128 railroad cars in 8 hours.

PETROLEUM

A large amount of the petroleum produced in Indiana has come from the Indiana portion of what is known as the Lima-Indiana oil field. This includes, in Indiana, portions of Grant, Blackford, Huntington, Wells, Adams, Jay, Delaware, Madison and Randolph counties.

This field reached its highest production in 1904, when over 11 million barrels were produced in the State, the larger part from this field. The annual production for the State is still in excess of one and one-third million barrels. The southwestern Indiana field, extending from Martin county through Daviess, Pike and Gibson counties, is becoming an important field and will probably be extended. Sullivan county contains an area which is producing both oil and gas. The oil in the Lima field is obtained from the Trenton limestone. In the northern and southern parts of the State some oil is obtained from the Corniferous and in the southwest-

ern portion from the Mississippian and the Pennsylvanian formations. Wells are being drilled on untried territory in Martin, Monroe, Lawrence, Jackson, Jennings and other counties. Much untried territory lies in the State, but it is possible to determine the structural conditions only in the non-glaciated region.

NATURAL GAS

The largest natural gas area in Indiana lies in the eastern portion of the State, in the counties of Delaware, Blackford, Jay, Madison, Hancock, Henry and Randolph. Gas has recently been obtained from wells in Lawrence county and in the southwestern oil field in Pike and Gibson counties. The eastern gas field of Indiana reached the peak of production in 1902, when the value of the gas produced was more than 7 million dollars. At the present time the value of its production is somewhat under one million dollars. Much untried territory exists in the State and lends encouragement to the hope that production may again soon be on the increase.

The largest amount of gas has been found in the Trenton sands. Some has been obtained from the Corniferous, some from the Mississippian and some from the Pennsylvanian rocks.

PEAT

Many of the shallow lakes, marshes and ponds which were left on the surface of northern Indiana following the retreat of the glacial invasion were later filled with an accumulation of vegetable matter. This vegetable matter was gradually transformed into peat, the so-called first stage in the formation of coal. The workable peat beds cover approximately 36,000 acres and contain nearly 3 billion cu.ft. Enormous fuel values are represented in this resource, as well as mull, which may be used as an absorbent, packing material, deodorizer, fertilizer filler, in the manufacture of gas, coke and ammonia.

CEMENT

Indiana ranks second among the States in the production of cement, producing more than three times as much as it consumes, though it consumes annually more than one barrel per capita. Portland cement is the principal kind produced, but a small amount of natural cement is manufactured. There are five active plants, located at Buffington, Stroh, Syracuse, Speed and Mitchell, and one under construction at Limesdale. The materials used are surface clays, marl from the lakes, slag from the iron smelters, hydraulic limestone from the Devonian formation and shale and limestone

from the Mississippian formation. With the present capacity, under normal conditions the production of cement in Indiana would exceed 10 million barrels.

BUILDING STONE

Indiana has attained an enviable position among the States of the Union as a producer of high-grade building stone. The oölitic limestone from the Salem formation, which is known as Indiana, Bedford or oölitic limestone, is highly praised by architects and builders and is widely used in the erection of both public and private buildings. Its uniform gray color, fineness of grain, freedom from planes of weakness, ease of carving, strength and durability recommend it to the builder. The best grades contain from 98 to 99 per cent of calcium carbonate and possess a crushing strength of 7000 lb. per sq.in. Two of the counties, Lawrence and Monroe, contain 36 large quarries which produce more than 70 per cent of all of the limestone used in the United States for building purposes. Fifty-five large mills prepare the stone for the market, handling more than 10 million cu.ft. per year. A recent order received by these mills includes enough dressed stone to fill 700 cars. The value of the stone for this contract is a little under one million dollars and it all goes into a single building.

The Indiana oölitic limestone has been used in nearly every State in the Union. It has been used in at least five State Capitol buildings, Indiana, Illinois, Georgia, New Jersey and Mississippi. The area occupied by this stone extends from Putnam county to the Ohio River, and its outcrop varies in width from a few rods to 14 miles. Its maximum thickness is about 100 ft. The Niagara limestone is a bedded stone which is quarried extensively in Indiana and is used for flagging, curbing, foundations, ashlar, piers, abutments and other purposes.

CERAMICS

Indiana produces a variety of ceramic wares, common, front, vitrified, ornamental and fire brick, totaling in value about 350 million dollars annually. Drain tile, encaustic tile, fireproofing, terra cotta, sewer pipe and stove lining are other important products. Pottery products manufactured are red earthenware, stoneware, yellow and Rockingham ware, white ware, C. C. ware, white granite, semi-porcelain, sanitary ware and porcelain electrical ware.

Indiana ranks sixth in ceramic production. The materials used in this industry in Indiana are the Knobstone shales, the Chester shales, the shales of the Pennsylvanian formation, the under or fire clays, gla-

cial till and kaolin. The Chester shales are used only to a limited extent, but their quality warrants a much more extensive utilization. The Pennsylvanian shales are used at Terre Haute in the manufacture of hollow block building tile, radial chimney blocks, partition tile, flue linings, drain tile, roof tile and paving brick and for many other purposes.

At Brazil the clay plants use fire clay from under the coal in the manufacture of front brick, sewer pipe, conduits, silo blocks, interlocking glaze tile and hollow blocks.

Some glacial till and shale are also used. The Knobstone shales are used at Martinsville, Brooklyn and other places. Surface clay and glacial till are used in the northern part of the State in the manufacture of drain tile and some other products.

LIME

Both quick and hydrated lime are manufactured in Indiana.

The limestones used for the manufacture of lime include the Niagara, the Mitchell and the Salem. There are other limestones, such as some of the limestones of the Chester group, which are suitable and have been used locally for lime. There are also deposits of marl which could be used for this purpose. The lime produced in Indiana is used in a number of industries, for building lime, glass manufacture, chemical lime, paper manufacture, sugar refining, tanning and agriculture. The production exceeds 100,000 tons per year. A portion is magnesian lime and a portion high calcium lime.

The Niagara limestone contains from 50 to 53 per cent of calcium carbonate and from 7 to 45 per cent of magnesium carbonate. The average of 5 samples contained 66.12 per cent of calcium carbonate and 26.38 per cent of magnesium carbonate.

The Salem or oolitic limestone contains for an average of five samples 98.11 per cent of calcium carbonate and 0.84 per cent of magnesium carbonate. The Mitchell limestone contains for an average of five samples 98.06 per cent of calcium carbonate and 0.45 per cent of magnesium carbonate.

GRAVEL AND SAND

The invasion of ice during the glacial period left in its wake in Indiana not alone destroyed or reversed drainages but large quantities of sand and gravel which have been of great value to the State. Building sand, ballast sand, foundry sand, glass sand, paving and other sands are well distributed and the production is more than $\frac{3}{4}$ million tons a year. The annual production of gravel exceeds 2 $\frac{1}{2}$ million tons, the greater part of which is obtained from the glacial deposits. In the unglaciated region some gravel is obtained from the Mansfield grit and from residual chert gravels produced by the weathering of the bedrock formations. Many of the streams which cross the non-glaciated area have their valleys filled with sand and gravel carried from the glaciated area.

This valley filling amounts in places to more than one hundred feet.

MARL

A secretion of white calcium carbonate, secreted largely by the plant *Chara*, accumulates on the floors of the lakes in Indiana and forms, with a slight mixture of clay and fine sand, beds of marl. The area extent

A COAL MINE WHICH PRODUCED 128 CARS, 612 $\frac{1}{2}$ TONS, OF COAL IN 8 HRS.—THE AMERICAN MINE AT BICKNELL, KNOX COUNTY, INDIANA

of the available marl beds of Indiana is approximately 7500 acres containing approximately 137,133,333 cubic yards.

The marls of Indiana furnish the calcium carbonate used in the manufacture of portland cement. They are suitable for the manufacture of quicklime, agricultural lime and other purposes.

KAOLIN

A variety of halloysite called "Indianate" occurs in more than half a dozen counties. The most important deposits are found in Martin and Lawrence counties. The kaolin has been used in the manufacture of ceramic wares, alum cake and for other purposes. A part of the deposit consists of a pure crystalline variety, but a great deal of it is stained a mahogany red by iron oxide.

The white kaolin is suitable for use in the manufacture of paper, paint pigments, ultramarine, filters, absorbents and buffing powders. The kaolin occurs at several horizons in the Mississippian formation and at the contact between the Mississippian and the Pennsylvanian formations.

MINERAL WATERS

There are many important mineral springs in Indiana. About 20 of them sell about \$500 000 worth of water per year.

At seven of the springs there are hotel accommodations for more than 2500 persons. Much of the water is sold for medicinal use. Favorite watering places are French Lick, West Baden, Trinity Springs and Martinsville.

OTHER RESOURCES

A fine grade of oil stones is produced from the sandstones of the Chester and the Mansfield groups. A factory for the manufacture of oil stones is located in the northern part of Orange county. Potash has been manufactured from shale in Clark county, but production is still in the experimental stage. Pyrite from which sulphur is obtained is a by-product of the mining of coal and may be obtained from shales. Paint pigments occur in limited quantities. A little gold and some precious stones have been obtained from the glacial drift in a few counties.

Chemical Industries of Indiana

By F. O. ANDEREGG

IN THE Hoosier State industries of an organic nature are most numerous and important. Of the organic chemical concerns in Indiana the pharmaceutical industry stands out rather prominently, and of the several companies engaged in this industry Eli Lilly & Co. of Indianapolis does the biggest business. It manufactures a complete line of pharmaceutical products and several alkaloids such as emetine, colchicine, hydrastine, cephaeline, sanguinarine, etc. It has made nearly all the atropine sulphate used in this country and in England during the war from jimson weed by a process of its own. This company also has a large biological department where a great variety of serums and antitoxins are made and distributed.

Eli Lilly & Co. has long appreciated the benefits to be derived from a research department and has equipped a fine building for its use. The science building is provided with an excellent assembly room for use of salesmen's schools and meetings of employees; it is available also for the use of local scientific societies which from time to time are invited to be the guests of this firm. An excellent library devoted largely to chemistry, physiology, botany, experimental medicine and other lines cognate to pharmacy is maintained for the use of the scientific staff.

LILLY & Co.'S CHEMICAL LABORATORIES

The second floor of the building is occupied by admirably equipped chemical laboratories for analytical and research work. Each analyst has an alcove which is practically a complete chemical laboratory in itself. Additional apparatus like balances, polariscopes, spectroscopes, refractometers, etc., are in specially built rooms readily available for use. A well-equipped electrochemical laboratory is installed on this floor. On the third floor there is a department of experimental medicine where the drugs and chemicals which cannot be standardized chemically are tested physiologically upon selected lower animals. Investigations are conducted extending over long periods of time having for their purpose the determination of the deterioration and keeping qualities of various pharmaceutical products. Laboratory research work on synthetic drugs

CULTURE MEDIA LABORATORY, BIOLOGICAL DEPARTMENT, SWAN-MYERS CO., INDIANAPOLIS

constitutes an important portion of the activity of the department of experimental medicine. The science building also provides quarters for an interesting laboratory for synthetical chemical research. With the installation of a noted expert in colloids this firm is preparing to carry on extensive research in the theoretical and practical development of this extremely important branch of chemistry.

As the inspection of crude vegetable drugs is a very important work in handling the enormous quantities of materials such as are necessary in manufacturing operations, the Lilly laboratories have maintained for the last 25 years an excellent botanical department which has quarters in the science building. The botanical laboratory proper contains large collections of authentic crude drug specimens, identified adulterations, substitutes, also standard herbarium specimens and an extensive collection of microscopic preparations of vegetable drugs. A conservatory is on the same floor for the purpose of propagating seedlings used in the study of medicinal plants and in work upon plant breeding. The botanical department, in addition to being charged with the inspection of crude drugs purchased for manufacturing, has also the supervision of extensive tracts of ground employed in raising drugs, and especially in experiments in drug plant breeding, with a view to improving the quantity of the medicinal principles.

OTHER LEADING CONCERNS

Another important concern also located in Indianapolis is the Swan-Myers Co. This firm manufactures a very complete line of pharmaceutical products which are used by the medical profession and by veterinaries. It also prepares a full line of biological products of a bacterial nature. The firm's products are sold throughout both Americas. The Pitman-Moore Co. is also located in the capital city and is engaged in the same sort of business, making a specialty of veterinary biological products. Other pharmaceutical concerns are the McCoy-Howe Pharmacal Co. of Indianapolis, the Lafayette Pharmacal Co. in the city of that name and the Central Pharmacal Co. of Seymour. Since the supply of chemicals from Germany has been cut off the Inland Alkaloid Co. of Tipton has perfected a number of processes for the manufacture of some of the mydriatic alkaloids. It has made notably large quantities of

BACTERIOLOGICAL LABORATORY, BIOLOGICAL DEPARTMENT, SWAN-MYERS CO., INDIANAPOLIS

atropine sulphate from stramonium or jimson weed. Its products are sold only through wholesalers.

OTHER PRODUCTS KEEP FIRMS BUSY

The Mishawaka Woolen Manufacturing Co. is engaged in making woolen and rubber footwear and is solving some interesting chemical problems in making its goods wear longer and stand better the disintegrating effects of time.

Varnish and similar products are made by the well-known concern of South Bend, the O'Brien Varnish Co.

The Dodge Manufacturing Co. of Mishawaka has been engaged 100 per cent in war work. Besides manufacturing marine engines, gun carriages, conveyor systems for powder plants, it has been making aeroplane parts, using a waterproof adhesive developed in its own plant and used in the construction of plywood. This plywood was used on the wings and fuselages of aeroplanes by both the Army and Navy. There is reason to believe the NC boats were made complete with Dodge veneer. This development grew out of trunk manufacture.

There are several plants distributed throughout central Indiana for the manufacture of strawboard. There is usually a large demand for this product, and the supply is limited only by the amount of raw material available.

Starch, glucose and by-products are made by the Union Starch & Refining Co. of Edinburgh.

There are many concerns engaged in the canning business. The most prominent of these is the Van Camp Co. of Indianapolis, which is also most interested in chemical control and development work. A good example of the soft drink manufacture is the Centlivre Beverage Co. of Fort Wayne, which makes the well-advertised drink called "That's it."

This city is also the home of the Rub-No-More soaps.

One of the most interesting firms engaged in organic chemical industry has been the Commercial Solvents Co. of Terre Haute, which has been using a unique method for producing acetone by the fermentation of carbohydrates which yield ethyl alcohol as the most important by-product.¹

The Prest-O-Lite Co. of Indianapolis is engaged in the manufacture of products of an organic as well as electrochemical nature. The name, Prest-O-Lite, has been associated with automobile service for many years. The use of acetylene for lighting and its wider application in oxy-acetylene welding are well known. The gas from the action of water on carbide is dissolved in acetone and stored in steel cylinders packed with a charcoal and asbestos filler. The cylinders are manufactured in sizes suited to various uses. The phenomenal growth of the Prest-O-Lite battery plant is indicative of the favor it has won with the public for automobile starting and lighting uses. During the past three years the plant floor space has increased nearly ten times. A proposed addition during 1920 will bring the total to 280,000 sq.ft. It is anticipated that the increase in facilities will enlarge the capacity to about 3500 batteries per day by the end of this year. The lighting and starting batteries are employed as standard equipment on 35 makes of motor cars and trucks. The elements consist of Faure type plates. In their manufacture lead oxide paste is applied to lead antimony grids. After a period of "setting" in dilute sulphuric acid, during which

the oxide is largely changed to sulphate, the positive plates are converted to lead peroxide and the negative to lead sponge by electrolysis. The positive and negative groups are assembled with wood separators of maximum porosity, thus preventing the lessening of capacity at low temperatures, as happens when partially porous material such as perforated hard rubber is used.

About 20 years ago Indiana ranked second among glass-producing States. With the decrease in supply of natural gas this industry suffered, although with the introduction of labor-saving machinery during the last few years it has begun to advance again. Two important firms making glass are the Ball Bros. Glass Co. of Muncie, which makes a specialty of glass jars for household use, and the Fairmount Glass Works of Indianapolis, which makes a variety of glass bottles.

The United States Encaustic Tile Co. of Indianapolis makes some very beautiful decorative art mosaic, tiles and bricks.

CEMENT

Located at Mitchell in the southern part of the state are two 10-kiln plants of the Lehigh Cement Co. with a capacity of two and a quarter million barrels of cement a year. The raw materials are from the Mississippian formation and include the massive Mitchell series limestone and the Knobstone (or New Providence) shales. These rocks are made into a cement which is notable for its whiteness and is in special demand for sidewalks and curbing.

This Mitchell limestone is of a very high quality, running consistently better than 96 per cent pure calcium carbonate. It is made into high-grade chemical and hydrated lime by the Mitchell Lime Co. of Chicago. The purity of this material makes a very even slaking lime well adapted for a great variety of chemical reactions. In making the hydrated material exactly the right amount of water is scientifically added. Then the very finely divided hydroxide is separated from any grit by air separation and is packed in 50-lb. sacks, which are very carefully sealed, preventing appreciable deterioration. The company's products are used very successfully in the manufacture of soap, paper, rubber, varnish, insecticides, also in oil refining, the dehairing of hides, sanitation and water purification.

A very interesting alloy is made at Kokomo by the Ellwood-Haynes Stellite Co. It contains cobalt and chromium somewhat analogous to nichrome and seems to have many of the properties of that alloy in regard to its resistance to the action of most chemicals. But it has other unique properties, the most important of which is its extreme hardness. Stellite does not lose its characteristic hardness even at red heat, making it probably the best high-speed tool metal known. Its chemical and electrical properties are being tested in the laboratories of the Purdue University, and it offers promise of many useful applications in both of these industries.

A good example of the testing laboratories of the State is furnished by the Fort Wayne Testing Laboratory Co., which carries out a great variety of chemical and physical tests and plant control experiments involving metals, fuels, foods, cement, water, etc.

The chemical industries of the northwestern part of the State are not taken up in this article, since they belong with the Chicago district as described in an article elsewhere in this number.

¹J. Ind. Eng. Chem., 11, 723, gives an account of this process.

Natural and Industrial Resources of Michigan

General Review of the Mineral, Metallurgical and Chemical Industries — Leading Products Include:
Iron, Copper, Salt, Alkalies, Halogens, Lime, Gypsum, Cement, Abrasives, Silica, Sugar,
Paper, Dyes and Organic Chemicals

Mineral Resources of Michigan

BY R. A. SMITH

MICHIGAN is one of the foremost States in the production of minerals and mineral products. She produces about thirty different mineral products. The total value of these in 1917, exclusive of pig iron, was \$185,511,101, and the value of pig iron shipped was \$18,300,501. The production of copper amounted to 268,508,091 lb., valued at \$75,622,256, and the shipments of iron ore amounted to 17,839,548 tons, valued at \$60,508,942. The total value of copper and iron was \$136,131,198, or nearly 74 per cent of the total value of the mineral products for the State.

The chief mineral products next in order of importance were salt, 16,078,136 bbl., valued at \$6,877,202; portland cement, 4,688,899 bbl. shipped, valued at \$6,122,887; coal, 1,374,805 tons shipped, valued at \$4,426,314; limestone and lime sold \$4,213,587; brick and tile products, \$2,846,264; sand and gravel, \$1,641,748; and gypsum, 375,803 tons mined and gypsum products sold, \$1,568,655.

The other less important mineral products in order of value are silver, bromine, sand-lime brick, calcium chloride, mineral waters, grindstones and scythestones, potash, trap rock, glass-sand, quartz, clay, sandstone, petroleum, natural gas, marble, graphite, precious stones, mineral paints.

In 1917 Michigan held first rank in the production of salt, bromine, calcium chloride and sand-lime brick; second in iron ore and grindstones and scythestones; third in copper, gypsum and gypsum products; fourth in limestone and lime; sixth in sand and gravel, and eighth in portland cement.

The development of some of the mineral resources began early. The production of coal began as early as 1836, copper in 1845, iron ore in 1850, salt in 1859, and gypsum in 1860. The quarrying of limestone for burning lime began in Monroe county almost with the settlement of Detroit in 1701. The development of some of the other mineral products was comparatively recent—sand-lime brick about 1903, potash as a by-product of the portland cement industry in 1917, and marble in 1918. Michigan contains other mineral resources as yet undeveloped—feldspar, pyrite, slate, granite, celestite—and many of the other resources are susceptible of much greater development.

IRON ORE

The iron ores of Michigan are chiefly hematite, but there are some limonitic ores. The iron ore districts are located in the Northern Peninsula. The ore is produced in six districts, which in order of importance are: the Gogebic, Gogebic county; the Marquette, Marquette county; the Iron River, Iron county; the Menominee, Dickinson county; the Crystal Falls, Iron county, and the Gwinn, Marquette county. The total shipments of

iron ore in 1917 amounted to 17,839,548 tons, of which the Gogebic Range contributed 7,003,838 tons, the Marquette 3,959,103 tons, the Iron River 2,525,741 tons, the Menominee 1,975,096 tons, the Crystal Falls 1,454,667 tons and the Gwinn 921,103 tons.

The total ore reserves Jan. 1, 1917, were estimated at 196,750,502 tons, of which 83,721,570 tons were developed ore, 107,954,081 tons prospective ore, and 5,132,343 tons ore in stock.

In 1916, 4,801,856 tons, or 25.4 per cent of the ore shipped, was of bessemer grade. The Gogebic Range contributed 3,933,594 tons, or 81.9 per cent, of the total bessemer ore produced, the Marquette Range (including the Gwinn District) 690,283 tons, or 14.4 per cent, and the Menominee 177,979 tons, or 3.7 per cent.

The average iron content of the ore as shipped was 53.03 per cent for the Gogebic, 52.43 per cent for the Marquette and 51.62 per cent for the Menominee Range.

COPPER

Prior to 1883 Michigan had produced 80.2 per cent of all the copper produced in the United States. In 1887 she was surpassed in production by Montana and in 1905 by Arizona. From 1845 to the close of 1917 Michigan produced 6,366,506,339 lb. of copper, or 25.27 per cent of the total production of copper of the country during this period.

The copper range extends from the northern extremity of Keweenaw Peninsula southwest through Keweenaw and Houghton counties into Ontonagon county. Copper-bearing rocks also occur on Isle Royale, in Lake Superior. The copper-bearing series comprise a thick succession of lava flows and interbedded sandstones and conglomerates. The copper deposits are unique in that they are the only large deposits in the United States in which the ore occurs chiefly as the native metal. The copper occurs in the cellular portions of the lava flows and in some of the beds of sandstone and conglomerate and certain shales.

Most of the lodes are low grade. The average content of copper recovered from the ore treated in 1917 was less than 1 per cent. The copper values, however, are relatively uniform in the lodes. This, together with the high concentration possible with native ore and the low cost of refining, makes the mining of such low-grade deposits profitable.

SALT

The salt resources are inexhaustible and comprise natural brines and beds of rock salt. Natural brines occur in several rock formations. The brines from the Marshall sandstone have been utilized most extensively in salt manufacture in Saginaw Valley. Formerly this region was the center of the salt industry. It was carried on in connection with the lumber mills, but with the decline of lumbering it has become relatively unimportant. The Marshall brines contain considerable per-

IRON ORE AWAITING SHIPMENT AT PRINCETON MINE

centages of earthy chlorides and an appreciable content of bromine. These brines are the source of all of the bromine and calcium chloride produced in Michigan.

The chief salt-producing district is along Detroit and St. Clair rivers, but the Ludington-Manistee district is also an important producer. Salt is produced from artificial brines derived from underlying beds of rock salt. In the Detroit-St. Clair rivers district, the rock salt beds have an average aggregate thickness of over 400 ft. In the Ludington-Manistee district the aggregate thickness of the beds is less than 50 ft. More than 800 ft. of rock salt was penetrated in a well at Onaway and over 300 ft. at Grand Lake, Presque Isle county. Salt was also struck at Alpena, Alpena county. The salt resources of these counties, though unlimited, have not been utilized.

LIMESTONE

Michigan has very large deposits of limestone. Unfortunately most of the deposits are located in the northern part of the State relatively distant from large markets. Many of the deposits, especially in the Southern Peninsula, are on or near cheap water transportation, and this partially compensates for the distance from markets. Only a few important deposits of commercial limestone occur in the southern half of the State.

The principal limestone district of the Southern Peninsula extends across the northern end of the Peninsula from Thunder Bay to Little Traverse Bay. In the Northern Peninsula, the deposits form a belt from 10 to 15 miles wide extending from Menominee county on the west along the northern shores of Lake Michigan and Lake Huron to Drummond Island. There are numerous very large and many smaller exposures of limestone in both districts. The limestone varies in composition from nearly pure calcium carbonate to calcium-magnesium carbonate or normal dolomite. The deposits along the shore of Lake Huron in Presque Isle county are remarkable not only for their extent and thickness but for their very high average purity. The greater part of the limestone belt adjacent to the lake shores in the Northern Peninsula is characterized by high magnesian limestones or dolomites. Some beds are very pure, but others are very siliceous. The northern part of the belt contains several relatively thick high calcium beds of limestone interbedded with light to heavy magnesian limestone.

In the Southern Peninsula limestone is quarried on a large scale at Sibley, near Detroit; near Bayport, Huron county; at Alpena and Rockport, Alpena county; near

Rogers, Presque Isle county, and along the south side of Little Traverse Bay. An important quarry is operated at Bellevue, Eaton county. In the Northern Peninsula large quarries are operated at Manistique and near Blaney, Schoolcraft county; at Hendricks and Fibern and east of Trout Lake, Mackinac county.

The stone is used chiefly for flux, chemical purposes, commercial lime, portland cement, carbide, road metal, concrete aggregates, ballast, etc. A large tonnage of low-silica stone is produced at Rogers, Presque Isle county, for fluxing purposes.

MARL OR BOG LIME

Marl or bog lime occurs in hundreds of lakes and swamps in Michigan. The deposits vary in size up to several hundred acres and to 50 ft. or more in depth. Many deposits contain an average of more than 90 per cent of calcium carbonate, but others are very impure. Though only a small portion of the deposits have been investigated, the aggregate area of proved marl deposits is over 27,000 acres.

Most of the early cement companies in Michigan used marl, but, because of cheaper operating costs, they have since changed to limestone wherever possible. The use of marl for correcting sour or acid soils promises to become of considerable agricultural importance.

COAL

The coal basin underlies the central portion of the Southern Peninsula. In the early days of the coal industry producing areas were in the vicinity of Jackson, Jackson county; Owosso, Shiawassee county, and Grand Ledge, Eaton county. In 1897 the development of the coal deposits in Saginaw Valley began and now most of the coal is produced in Bay, Saginaw and Tuscola counties.

There are a number of coal beds, but most of them are too thin to mine under present conditions. The minable coal occurs in small basins or troughs varying from 100 to 2000 acres or more. The coal is a high volatile non-coking bituminous coal. It is an excellent domestic and a good steam coal.

GYPSUM

Large deposits of gypsum occur in the vicinity of Grand Rapids and Grandville, Kent county; in Iosco and Arenac counties, and in St. Ignace Peninsula and to the eastward on St. Martins Island, Mackinac county. Beds of gypsum apparently of commercial thickness and extent are also reported in Tuscola, Eaton and Ionia counties. The deposits are extensively developed in the Grand Rapids-Grandville district and at Alabaster, Iosco county. There are numerous beds in each district and several are of workable thickness. The largest beds are about 25 ft. thick. A portion of the crude gypsum is ground for land-plaster but most of it is calcined for stucco, mixed wall-plasters, plaster board, building block, calcimines and other gypsum products.

SAND AND GRAVEL

The sand and gravel deposits of Michigan are inexhaustible. The most important deposits occur in ridges known as "hogbacks" or eskers, in irregular hills called kames, and in outwash plains, deltas, and beach ridges—features resulting from water action during the last glacial invasion. Large deposits occur in nearly every locality. In the vicinity of industrial cen-

ters and along lines of rail and water transportation, the deposits have been extensively developed for general building purposes and concrete construction. Hundreds of gravel deposits have been developed for road building.

SILVER

Silver occurs in the deposits of native copper, chiefly as intergrowths of the two metals. The entire production of silver is derived from the copper ores.

BROMINE

The brines of the Marshall and Berea sandstones contain appreciable quantities of bromine. All of the bromine, however, is produced in Saginaw Valley from Marshall brines in connection with the salt and chemical industries. The chief centers are Midland, Saginaw and St. Charles. In 1917 Michigan produced 82.2 per cent of the bromine produced in the United States.

CALCIUM CHLORIDE

The Marshall brines, in addition to bromine, contain considerable percentages of calcium chloride. This is recovered as a by-product of the salt and chemical industries in Saginaw Valley. In 1917 this region produced nearly three-fourths of the calcium chloride produced in the United States. The chief centers are at Midland and Saginaw.

POTASH

A considerable amount of potash is derived from leaching wood ashes, but in 1918 the production of potash as a by-product of the portland cement industry began at Newaygo, Newaygo county. There are large possibilities for a much greater production from the other portland cement plants which have not yet provided for the recovery of potash from escaping flue dust.

MINERAL AND SPRING WATERS

At Mt. Clemens, Ypsilanti and Detroit mineralized waters are produced in large quantities for bathing and medicinal purposes. Mineral and spring waters are also produced at a number of other places in the State. Some of the mineral waters are strongly mineralized and compare favorably with other famous mineral waters.

GRINDSTONES AND SCYTHESTONES

Grindstones and scythestones are produced in large quantities from certain beds of sandstone in Huron county. There are large deposits in the vicinity of Grindstone City and Port Austin.

CRUSHING PLANT AND STORAGE PILE OF THE MICHIGAN LIMESTONE & CHEMICAL CO. AT CALCITE

CLEVELAND STONE CO. WORKS AT GRINDSTONE CITY—SEAT OF GRINDSTONE AND SCYTHSTONE INDUSTRY IN MICHIGAN

TRAP ROCK

There are inexhaustible deposits of trap rock in the western part of the Northern Peninsula. Crushed trap rock for road metal and concrete aggregates is produced at Marquette and Negaunee, Marquette county. A large amount of trap rock is produced in connection with copper mining. The marketed production, however, is small because of the remoteness of the deposits from large markets.

GLASS-SAND

Large deposits of pure white silica sandstone occur in Wayne and Monroe counties. The sandstone is quarried, crushed and washed for glass-sand at Rockwood, Wayne county, and near Steiner, Monroe county. The sandstone is composed of pure silica sand with very little lime or other cementing material. The washed product from some beds contains over 99 per cent silica and only 0.001 per cent of iron. It is used chiefly for the manufacture of plate glass. Because of its exceptional purity it was used during the war by the U. S. Bureau of Standards for the manufacture of optical glass.

QUARTZ

Pure white quartz occurs in large veins at many places in the western parts of the Northern Peninsula. It is quarried and ground near Ishpeming for wood filler, scouring polishes, etc. Analyses show that the quartz rock is practically pure silica.

CLAY

There are extensive deposits of surface clays, but most of them are high in lime and are suitable only for the manufacture of common brick and tile. In some of the deposits, leaching has removed the lime to considerable depths. Such deposits are adapted for the manufacture of higher grade products. In Ontonagon county some of the surface clays are of the slip variety and are utilized for glazing purposes. Surface clays are used at many places for the manufacture of common brick and tile. Most of the common brick are produced in the vicinity of Detroit.

SHALE

There are relatively few deposits of shale because most of the rock strata are concealed by the cover of glacial material. The only important deposits of shale in the southern part of the State are in Branch, Jackson, Eaton, Ingham, Genesee, Shiawassee and Sanilac

BANKS OF THE CRYSTAL SAND & GRAVEL CO., INC.

counties. There are numerous exposures of shale in Antrim, Charlevoix, Emmet, Cheboygan and Alpena counties, but these are distant from large markets. Shale also occurs in association with coal seams.

Shale is quarried near Coldwater and Union City, Branch county; near Ellsworth, Antrim county, and at Paxton, Alpena county, for use in the manufacture of portland cement, and at Jackson, Jackson county; near Flushing, Genesee county, and at Grand Ledge, Eaton county, for vitrified brick, tile and conduit. Deposits favorably situated in relation to markets and transportation occur at Williamston, Ingham county, and near Corunna, Shiawassee county. Shales associated with the coal beds in Saginaw Valley have been utilized for vitrified brick and tile products.

SANDSTONE

There are numerous exposures of sandstone in Hillsdale, Calhoun, Jackson, Ionia and Huron counties, in the Southern Peninsula. Most of this sandstone, because of its unstable color, is suitable only for rough building purposes. All of the numerous early quarries are now abandoned.

Unlimited deposits of mottled red and brown sandstone occur along the shores of Lake Superior in the Northern Peninsula. The stone has pleasing and permanent colors, but chiefly because of the great distance from markets the industry has declined until there is but one active quarry.

PETROLEUM

Petroleum has been struck in small quantities in numerous places in the State, but only at Port Huron has the quantity been sufficient for commercial development. The total output is insignificant.

NATURAL GAS

A small quantity of gas accompanies the oil produced at Port Huron. In several localities gas is found in small quantities in the glacial drift. The total production of natural gas is unimportant.

MARBLE

Numerous deposits of *verde antique* marble occur some miles northwest of Ishpeming, Marquette county. Production began in 1918. The marble is composed of serpentine and dolomite, the results of alteration of peridotite rocks. It displays an intricate system of veins and stringers of white dolomite in light to dark-

green serpentine. It is massive in character and of excellent quality. The polished product compares very favorably with the best domestic and imported *verde antique*.

GRAPHITE

Graphite occurs in slates in Baraga county. The graphitic slate is quarried and ground for paint material. No attempt has been made to recover the graphite from the slate.

PRECIOUS STONES

Chlorastrolite, thompsonite, and some semi-precious stones are produced in small quantities in the copper-bearing region. Chlorastrolite is a beautiful mottled-green gem stone, peculiar to the Lake Superior copper-bearing district. The total value of the annual production of gem stones is very small.

MINERAL PAINTS

Certain of the iron ores in the Northern Peninsula are suitable for the manufacture of paint. Formerly several thousand tons of these ores were produced annually and sold for the manufacture of paint pigment.

SLATE

Extensive deposits of slate occur in Baraga county. The slate is very black, of fine texture and permanent in color. It appears to be of superior quality and suitable for roofing and other purposes for which slate is adapted. Prior to 1888 a number of slate quarries were operated for several years near Arvon, Baraga county. Apparently because of inefficient methods of quarrying, great distance from markets and lack of cheap transportation facilities the industry was unprofitable.

GRANITE

Extensive exposures of granite occur in many localities in the western part of the Northern Peninsula. Several unsuccessful attempts have been made to develop some of the deposits, but no production has been reported for many years.

PYRITE

Pyrite occurs in considerable abundance in some of the coal seams and associated rocks and also at certain horizons of the Antrim black shale. At some of the coal mines, the recovery of lump pyrite offers commercial possibilities. The most promising source of recovery is at the coal washery at Saginaw. Tests show that the refuse contains about 30 per cent of pyrite and that a concentrate containing considerably over 40 per

CRUSHING PLANTS OF THE MICHIGAN ALKALI CO. AT ALPENA

FALLS ON MENOMINEE RIVER ABOVE MANSFIELD

cent of sulphur is possible. Probably the pyritic waste from the different mines would be sufficient to supply a concentration plant.

CELESTITE

Celestite occurs as scattered masses in some of the limestone and glass-sand quarries in Wayne and Monroe counties. At Rockwood, Wayne county, the mineral occurs in masses of sufficient abundance to warrant recovery. No production of celestite, however, has been reported.

FELDSPAR

There are deposits of potash feldspar near Republic in sec. 22, T.47 N., R.29 W., Marquette county, and in sec. 8, T.46 N., R.41 W., Gogebic county. An unsuccessful attempt was made many years ago to develop the deposit near Republic. Probably further investigation in the Northern Peninsula would result in the discovery of other deposits of potash feldspar.

WATER POWER

Water power has been extensively developed on the St. Joseph, Kalamazoo, Grand, Muskegon, Manistee, Thunder Bay, Au Sable and Huron rivers in the Southern Peninsula and on the Menominee, Carp and St. Mary's rivers in the Northern Peninsula. Large powers have been developed on many of the other rivers in the State. There is an abundance of undeveloped water power on these streams, notably the Escanaba, Ontonagon and Taquamenon, and the water powers on the Muskegon, Manistee, Menominee and Au Sable rivers also are susceptible of much greater development.

Salt, Bromine and Calcium Chloride in 1918'

The production of salt (in short tons) in the United States during 1918 was as follows:

Grade	United States	Michigan
Manufactured (evaporated).....	2,724,203	1,059,872
In brine.....	2,830,600	
Rock salt.....	1,683,941	
Total	7,238,744	2,403,125

Bromine was made as usual from bittern left after extracting salt from the brine pumped from deep wells at Midland and Saginaw in Michigan; at Pomeroy in Ohio; Mason, Hartford and Malden in West Virginia; 1,727,156 lb. of bromine (either as the free element or its salts) was produced in 1918.

Calcium chloride, containing 2 to 6 per cent of magnesium, is recovered as a by-product in the manufacture of salt and bromine in the localities mentioned above. There was produced in 1918 26,624 tons.

Chemical Industries of Michigan

By W. L. BADGER

IN GENERAL, it would seem that in Michigan there is represented practically every important chemical industry, organic and inorganic. In many of the basic industries Michigan is either first or in the first two or three of all the States. Raw materials of all sorts are plentiful, the State is not far from the coal fields, and is almost midway between the great markets of the East and the mid-West. Among the many and various chemical and allied industries the following deserve to be specially mentioned:

SALT

The history of salt manufacture in Michigan goes back to 1838, when the State appropriated \$3000 to bore for salt at one of the salt springs. This work was continued for several years, but never gave any results. The first private plant to make salt was at Grand Rapids in 1840, but its life was short. In 1859 the industry was revived, aided by a State bounty; and though the bounty was not continued long, the industry continued to thrive till in 1905 the State led all her sister States in quantity of salt produced, and in 1906 in value of product. This position it has kept ever since. An important feature in the growth of the salt industry was the utilization of waste steam from sawmills. To dispose of waste the sawmills built incinerators; and the next idea was to burn the waste under boilers and use the steam for salt making. Hence we find the largest number of salt companies and the largest total number of grainers in the period from 1830 to 1895. Since then the industry has gradually concentrated into the hands of fewer and fewer companies, which make salt as a primary product and not as a by-product as in the days of the lumber industry.

The most important source of salt in Michigan is the Salina formation of rock salt. In some districts the wells are in higher strata; and in the Saginaw Valley the brine comes from flowing wells. The Salina is, however, the largest and purest deposit. In many cases underground waters flow into the salt beds to yield the brine, but in the majority of cases the brine is artificially formed by pumping water down to the salt layer. Practically all plants in the State work on brines running from 95 to 100 per cent saturated; many never fall more than a few tenths of 1 per cent short of complete saturation. At one of the largest plants in the State, a few years ago the question came up of filtering the water fed to the wells in order to get a cleaner brine. From the records of the amount of salt produced the size of the cavity in the salt bed was estimated; and it was found that if the water spread out evenly over the surface of the cavity, and the brine was drawn evenly from the bottom of the cavity, it would take about three years for the filtered water to appear at the top of the well.

The beds are worked around Detroit and along the St. Clair River. South of Detroit the salt suddenly disappears; and to the north and east the beds rapidly get deeper. Around Detroit the Salina rock salt is at 1000 to 1500 ft. and is 100 to 400 ft. thick. Along the Lake Michigan side the salt reappears, so that the State has three well-marked salt districts—the Detroit district, the Saginaw district and the West district.

'U. S. Geological Survey Bulletin, by Ralph W. Stone.

EARLY PROCESSES OF SALT MAKING

Only in the very early days was salt made in the kettle. The next development was the pan—some 20 to 30 ft. wide, 100 to 150 ft. long, and 12 to 18 in. deep. They were direct fired, and the salt was raked out by hand. Little or no salt is now made in this apparatus, though up to a short time ago old salt pans were still standing along the St. Clair River.
